But this characterization is not adequate to account for the rather macabre effects found in the newspaper report in (6b) beside the relatively unexceptionable (6a):

(6a) The woman had lived with the dead man for two years
(6b) The woman had lived with a dead man for two years

Still less can it account for the fact that on occasion the presence or absence of *the* seems to indicate the difference between subject and object, as in (7):

(7a) This man is in charge of my brother
(7b) This man is in the charge of my brother

In (7a) *this man* has control of *my brother*; in (7b) *my brother* has control of *this man*. So what does *the* really mean? Does it even make sense to ask such a question?

Take a more complex example: the word *last* is multiply ambiguous: apart from its use as a noun or a verb, it can function as an adjective meaning either 'final' or 'previous', as illustrated in (8):

(8a) This is your last chance
(8b) Your last example surprised me

This ambiguity can result in dialogues which have strikingly different interpretations, as in the alternatives in (9):

(9) Q "What were you doing in Paris?"
A1 "Oh, I was collecting material for my last book"
A2 "Oh, I'm collecting material for my last book"

Answer 1 is itself ambiguous, with either meaning possible for *last* (though 'previous' is the more easily accessible); Answer 2 has only the interpretation that the book under discussion is planned to be the final one I write. The difference must be attributable to the contrast between the past and the present tense, as that is the only way the sentences differ, but it's not obvious why sentences should be ambiguous or not depending on the tense they contain.

Linguists thrive on such ambiguity, as it regularly provides evidence for structural differences that may not be otherwise apparent. A simple example is provided by the inscrutable notice outside our local school, given in (10):

(10) This school accepts girls and boys under six

Whether the school accepts girls of any age but only small boys, or no children over six is indeterminate without more information. As we shall see under the section 'Describing Knowledge of Language,' (10) has two quite different syntactic structures corresponding to the two meanings. Similarly the fact that (11) has a number of different interpretations can give us clues as to how to analyze the various possibilities:

(11) My son has grown another foot

If my son has become taller, the example is parallel to (12a); if he is a freak or a remarkably successful gardener, there are other possibilities, as shown in (12b) and (12c), suggesting that *another foot* in (11) may be correctly analyzed either as a measure phrase or as a direct object:

(12a) He has grown by another foot
(12b) He has grown a third foot
(12c) Another foot has been grown (in this flowerpot)

Such differences of interpretation make the complexity of our knowledge apparent, but unambiguous examples can be just as illuminating and can simultaneously provide evidence against the traditional philosophical claim that meaning can be adequately treated in terms of truth. Thus, we know that (13):

(13) My first wife gave me this watch

suggests rather strongly that I have been married more than once, but I can utter it truthfully despite having been married only once: my only wife is presumably my first wife. The example is misleading, not false, and so implies that there is much more to meaning than mere truth. As shown by Chomsky's (1957) famous *Colorless green ideas sleep furiously,* structure and meaning (syntax and semantics) can dissociate, so we also know that, despite being initially plausible and syntactically unexceptionable, (14) is meaningless:

(14) More people have visited Moscow than I have

All the preceding examples illustrate both our knowledge of vocabulary and how it interacts with (syntactic) structure. The responsibility of linguistics is to describe the full range of such facts, not just for English, but for all human languages. Then, in virtue of its scientific pretensions, it has to (attempt to) explain why these facts rather than any others are the ones that occur – again both in English and in other languages. To do justice to the richness of what we know, it is necessary to distinguish not just the lexicon and the computational system, but to differentiate among syntax, semantics, morphology, phonology and phonetics, and to relate this knowledge to pragmatics – how we interpret utterances in context.

Take our knowledge of morphology, the internal structure of words. We know that *thick, thicker, thickest,* and *thicken* are all words of English, but that there is no *thinnen* to accompany *thin, thinner, thinnest*. We know that *thick* relates to *thicken* and that *rich* relates to *enrich*, whereas *richen* is slightly odd, and *enthick* is impossible. This knowledge can't just be a result of our never having heard *thinnen* or *enthick* before, you may never have heard *texted* before, as in "I've just texted an urgent message to Fred", but you know that that **is** possible. As linguists, we may also know that some languages, such as Vietnamese, have almost no morphology: words in this language have none of the internal structure characteristic of affix-rich items such as *indecisiveness* or *rearranged*. On the other hand, some (polysynthetic) languages, such as Inuktitut (Eskimo) or

Mohawk pile one affix on top of another so that words are often strikingly complex, and correspond to whole sentences in English. Baker (2001: 87) gives the Mohawk example in (15) with the meaning "He made the thing that one puts on one's body ugly for her":

(15) Washakotya'tawitsherahetkvhta'se'

Our knowledge of phonology, the sound structure of language, is equally rich. We know that *past, spat,* and *stap* are possible words of English, indeed they all exist; that *stip* and *stup* are also possible words, even though they happen not to exist; but that *satp, ptas* and *tpas* are not even possible words. Apart from knowing the segmental make-up of words, we also have knowledge of 'supra-segmentals': that *photograph* is stressed on the first syllable, *photographer* on the second, and *photographic* on the third. Two points need to be made: first, we 'know' this in the sense that we produce the correct pronunciations on demand, and we recognize that deviations from these pronunciations are slips of the tongue or foreigners' mistakes; that is, knowledge of language need not be immediately available to conscious introspection. Second, the characterization in terms of 'first', 'second', and 'third' syllable is actually not the correct theoretical characterization of our knowledge. As we shall see below, rules of grammar (including phonology) cannot count.

We know more. In an example such as (5a) above, *My friend likes the penguins*, we have to account for the pronunciation of *the* before the initial 'p' of *penguins*: a pronunciation rather different from that of the same lexical item *the* when it occurs before a vowel, as in *My friend likes the otters*. Knowledge of this kind is supplemented by phonetic knowledge which is even harder to bring to consciousness: that the 't' in *photographer* is aspirated, but the 't' in *photograph* is not; that the 'r' in *grime* is voiced, but that in *prime* it is slightly devoiced; that the vowel is longer in *wed* than in *wet*. Such facts belong to the domain of phonetics, the field that deals with the sound properties of language in general, rather than the sound structure of a particular language.

Our phonological knowledge is not self-contained, but may interact in complex ways with our knowledge of the rest of the grammar. We know that (16a) has an alternative pronunciation of the kind given in (16b), where *is* is 'contracted' to*'s*, but that (17a) cannot be matched by the impossible (17b) (impossible is indicated by the asterisk), despite the apparent similarity of the examples:

(16a) The prime minister is a war criminal
(16b) The prime minister's a war criminal

(17a) The president is a war criminal and the prime minister is too
(17b) *The president is a war criminal and the prime minister's too

An understanding of such asymmetries requires investigation of the relation between syntactic and phonological processes, and relies on an analysis of empty categories: entities that have syntactic and semantic properties but are silent.

In addition to phonology and morphology, we need to account for the (semantic) fact that sentences have meaning. The examples in (18) exploit most of the same words but their meanings are radically different:

(18a) My friend likes the penguins
(18b) The penguins like my friend
(18c) My friend doesn't like the penguins

Moreover, the semantics is 'compositional' – except for idioms, the meaning of a sentence is a function of the meaning of its parts, and their syntactic configuration. The meaning difference between (18a) and (18b) is dependent on which item is subject and which object, notions that can be defined syntactically. In fact, life is a little more complicated than that, as the semantic interpretation of 'subject' is not uniform, and we need to advert to 'thematic relations' involving ideas of agentivity and patienthood, as shown by the minimal pair in (19):

(19a) John undertook the surgery reluctantly
(19b) John underwent the surgery reluctantly

John is the subject in both sentences, but is the agent (the surgeon) in the former, and the patient (in both senses) in the latter. These relations are internal to a single sentence, but we also need to relate (the meanings of) different sentences. There are two possibilities: relations which depend on the meaning of individual words, and relations which are purely sentential in that they are independent of such lexical relations. An example of the former is illustrated by (20):

(20a) Mozart persuaded da Ponte to write a libretto
(20b) Da Ponte intended to write something

where (20b) follows, by virtue of the meaning of *persuade* from (20a). An example of the latter is provided by pairs such as (21a) and (21b), where the truth of (21a) guarantees the truth of (21b):

(21a) Torture is immoral and should be illegal
(21b) Torture is immoral

In the next section, I will outline some of the descriptive mechanisms exploited by (generative) linguistics; then I will try to show how we can approach an explanation for at least some phenomena, looking at

a range of examples from English and elsewhere, and use this extension to substantiate the claim that linguistics is a science. Throughout, I shall concentrate on **syntax**. Phonology and phonetics, morphology, and semantics are rich disciplines in their own right, each with a massive literature, but the essence of the analysis of sentences is their **syntactic structure**. And life is finite.

Describing Knowledge of Language

Sentences have structure of various kinds. Returning to the example, *My friend likes the penguins*, we need to describe it in different ways at several distinct 'levels of representation': phonological, semantic, and syntactic. Thus, it can be pronounced in a variety of ways – with stress on *friend* or on *penguins*, for instance, with concomitant differences of interpretation. Restricting attention to the syntax, it is intuitively clear that *my* and *friend,* and *the* and *penguins* 'go together' in a way that *friend* and *likes,* and *likes* and *the* do not. Each initial word of *My friend* and *the penguins* enables us to pick out some individual or individuals in the world, whereas *friend likes* and *likes the* have no such function within them. This intuition is accounted for in terms of 'constituency' represented by means of a simplified tree diagram of the kind in (22):

(22)

The top of the tree (IP) indicates that the whole sequence "*My friend likes the penguins*" is an 'I(nflection) P(hrase)'{it used to be called 'Sentence', but the terminology has changed to reflect changes in our understanding}. The IP 'branches' into an NP and a VP, where 'NP' means 'Noun Phrase', that is a sequence consisting of a Noun (N) and something else, and 'VP' stands for 'Verb Phrase', that is a sequence consisting of a Verb (V) and something else, here in this instance another Noun Phase. The verb is the (present-tense) form *likes*, and the two Noun Phrases each consist of a Noun (here the singular *friend* and the plural *penguins*) preceded by a 'Det(erminer)', respectively *my* and *the*. Each of 'IP', 'NP', 'VP', 'N', etc., are referred to as 'nodes' in the tree; IP, NP, and VP, etc., are said to 'dominate' everything below them, and to 'immediately dominate' everything immediately below them. So VP dominates all of V, NP, Det, N, *the,* and *penguins*, but immediately dominates only V and NP, which are known as 'sisters'. Once one has got used to the jargon, the advantages of such an analysis are many: it simultaneously shows the linear sequence of items – the order they come in – and the relationships among the component parts: so *the* and *penguins* are more closely related, by virtue of being NPs, than are *likes* and *the* which do not form a 'constituent' of any kind. A constituent is defined as any sequence of items that can be traced exhaustively to a single node in the tree: *likes* and *the* can be traced back to VP (and indeed IP), but these nodes dominate other material, too (*penguins*, for instance) so *likes the*, like *friend likes,* are not constituents.

We now have an explicit way of characterizing the example *This school accepts girls and boys under six*. The two interpretations of the object, *girls and boys under six,* can be represented with different constituent structure as in (23):

(23a) [girls] and [boys under six]
(23b) [girls and boys] [under six]

where the brackets mark the constituents, and indicate that the 'scope' of *under six* is respectively either just *boys* (23a) or includes *girls and boys* (23b).

In addition to this syntactic constituent structure, there is morphological structure to deal with: the fact that *penguins* is plural is marked by the addition of the suffix *–s* to the base *penguin*, and the opposite order (with *s-* prefixed to *penguin* to give *spenguin*) is impossible (in English). Investigating the full range of such facts in the world's languages is a matter of intensive research, and addresses the same immediate task of accounting for how it is that native speakers can have the intuitions and make the judgements of well- and ill-formedness that they do.

This last point bears elaborating. One of the surprising facts about our linguistic ability is that it extends to knowing what is impossible as well as what is possible: we have intuitions of ill-formedness or 'negative knowledge'. I have already traded on this fact in assuming that, even though you had probably never heard either example before, you would agree that *Giraffes have necks long* is wrong, whereas *I've just texted an urgent message to Fred* is acceptable. The point can be generalized: the fact that one can recognize mistakes and distinguish them from new but well-formed creations is evidence for the rule-governed nature of the language faculty. Mistakes presuppose norms, or rules. It is also noteworthy that there are 'impossible' mistakes: some logically possible errors just don't happen, even though one might expect them to. Consider an example from

language acquisition and the task of the child in working out how questions and statements of the kind in (24) are related:

(24a) The children are playing truant
(24b) Are the children playing truant?

There are all sorts of hypotheses children might entertain: move the auxiliary (*are*), move the third word, permute the first and second constituents, and so on. The kinds of mistake that children do make, however, show that their hypotheses overlap with these in interesting ways. First, they sometimes make mistakes of a kind for which there is no obvious pattern in the input, even though they may be theoretically well motivated: examples such as the 'auxiliary copying' in (25):

(25a) Is the steam is hot?
(25b) Are the children are playing truant?

Second, they never try out any hypothesis that would involve them in counting: their attempts always range over modifications of linguistic structure, never of mathematical structure. It seems that all rules in all languages are what is called 'structure-dependent' – they depend on notions such as constituent, Noun Phrase, and so on, but **not** 'third word'. Moreover, children seem not to need to learn this fact – it is a principle that guides their language acquisition from the start: it is innate. Claims of innateness have been unnecessarily controversial in modern linguistics. No one doubts that humans are innately (genetically) different from cats, chimpanzees, and dolphins, and that this difference underlies our ability to acquire language. Equally, no one doubts that humans acquire different languages depending on the environment they are brought up in: if children are brought up in Turkey rather than Greece, they learn Turkish rather than Greek. It is obvious that both nature and nurture have a crucial role to play. Where controversy is justified, and where empirically different claims can be tested, is in the detail of what needs to be ascribed to the child's 'initial state', of what precisely is innate and what has to be acquired on the basis of experience. Explaining structure-dependence is an area where innateness has been repeatedly (and controversially) defended with a form of argument based on the 'poverty of the stimulus' – the idea that we end up knowing things that it is impossible, or at least implausible, to think that we could find in the input. Consider examples more complex than those above, such as (26):

(26a) The children who were naughty are playing truant
(26b) Are the children who were naughty playing truant?

If 'moving the third word' or 'moving the (first) auxiliary' were really the correct way of characterizing the relation in (24) one would expect to find example mistakes like that in (27):

(27a) Who the children were naughty are playing truant?
(27b) Were the children who naughty are playing truant?

Such mistakes simply do not occur. Of course, it is always (usefully) dangerous to say that something does not happen: it may happen in the next utterance one comes across. But this means that the claim is eminently falsifiable (see below), and can anyway be checked by looking for relevant counterexamples in the literature. A nice example of this kind is provided by Neeleman and Weerman's (1997) account of acquisitional differences between Dutch and English. They predicted that Dutch children should, and English children should not, produce sentences with an adverb intervening between a verb and its object, as in (28):

(28) I will eat quickly the yoghourt

They ransacked the largest international corpus of child data in checking their predictions, and happily found no exceptions.

Formalizing our knowledge of language demands a complex toolkit, only a tiny fraction of which has been given here, but such formalization is a necessary prerequisite to finding explanations, to assimilating linguistics to the scientific enterprise. Given the tools developed here, we can make general hypotheses about the nature of language and begin to test them on a wider range of data from English and elsewhere.

Explanation in Language

Examples involving structure-dependence enable one to address the demand for explanation in addition to description. Let's pursue the issue by looking at the occurrence of items such as *any, ever,* or *anything* in English (so-called 'Negative Polarity Items'). At a descriptive level, it is sufficient simply to contrast possible and impossible sentences of the sort seen in (29a) and (29b), where those in (29a) are fully acceptable but those in (29b) are ungrammatical, or infelicitous, or just wrong:

(29a) John ate something/ some salad
(29b) *John ate anything/ any salad

But *why* is there this contrast? The example in (30) shows that *any(thing)* can occur happily enough in negative statements, but it occurs unhappily in positive statements:

(30) John didn't eat anything/ any salad

Looking at such negative examples, the generalization seems to be that *any(thing)* needs to occur with (be 'licensed by') a negator. But such an account is inadequate in two different ways: first, (31) shows that it is not just negators that are relevant, but a variety of elements behave in a similar fashion. This class includes questions, conditionals, and other items that there is no space to characterize:

(31a) Did John eaten anything/ any salad?
(31b) If John ate anything/ any salad, I'd be amazed
(31c) Everyone who has any sense has left already
(31d) John denied having eaten any of the cakes

Second, even if we restrict ourselves to negatives, it still seems that life is more complicated than we might wish – (32a) is unsurprisingly fine but, despite being negative, (32b) is unacceptable and none of (32c) to (32e) is acceptable:

(32a) Something/ some spider bit him in the leg
(32b) *Anything/ any spider didn't bite him in the leg
(32c) *Anything is annoying me
(32d) *Anything isn't annoying me
(32e) *John denied any of the accusations

That is, our first approximation that *any* needs to be licensed by a negative fails in both directions – some sentences with negatives do not allow *any*; some sentences without a negative do allow *any*. The next obvious assumption might be that *any(thing)* has to be **preceded** by a negator of some kind (*not* or *n't* here), but (33) shows that this hypothesis is inadequate: it works for (33a) and (33b) but not for (33c) or (33d) – where *nothing* is another negator:

(33a) The fact that he has come won't change anything
(33b) Nothing will change anything
(33c) *The fact that he hasn't come will change anything
(33d) *That nothing has happened will change anything

The examples in (33a) to (33d) suggest another possibility: perhaps the negator has to be in the same clause as the item (*any*) being licensed? In (33a), the negator and *anything* are in the same clause (compare "*This won't change anything*"), whereas in (33c) and (33d), the negator is in a different clause. We are getting closer, but (34) shows that this is still inadequate as an explanation, as here the negator and *anything* are blatantly in different clauses, but the result is well-formed.

(34) I don't think he has eaten anything

The claim that the negative (or other item) must be in the same clause as *any* fails: some sentences have the negative in a different clause and are nonetheless grammatical; some have the negative in the same clause and are ungrammatical. The correct explanation necessitates an appeal to the notion of 'c-command,' a relation between 'nodes' in a tree. To make this comprehensible and plausible, we need to introduce a little more of the technical machinery of generative grammar.

The representation of sentence structure in terms of trees of the kind shown in (22) can obviously be extended to show the structure of (29a), as shown in (35), where the only novel feature is the uncontroversial claim that *some* is a kind of Determiner:

(35)

More complex sentences require more complex configurations. Thus, the salient property of an example such as (33a) '*The fact that he has come won't change anything*' is that the subject is not just a noun or noun phrase, but a noun phrase containing another sentence '*he has come*'. To a first approximation it would have the (simplified) form given in (36), and the ungrammatical example in (33c) **The fact that he hasn't come will change anything* would be characterized by the tree given in (37):

(36)

Some of the details of the tree have been included for the sake of those who are already familiar with syntax. So the Complementizer Phrase (CP), optionally headed by a Complementizer such as *that*, and the I' (a constituent intermediate in size between a sentence (IP) and an Inflection element like *will*) are there for

the *cognoscenti*. But two things in these trees are important for everyone: first, that they contain a constituent Neg(ation), itself a subpart of a Neg-P(hrase); and second, that it makes sense to talk of one item being higher in the tree than another. That is, in (36), the 'Neg' is higher in the tree than *anything*, whereas in (37) the 'Neg' is lower in the tree than *anything*.

(37)

To make this account rigorous, we need to define exactly what is meant by 'higher' and 'lower', and that is what is meant by 'c-command': a node A in a tree c-commands another node B if and only if the first branching node dominating A also dominates B. In (36), Neg c-commands *anything* because the first branching node above Neg (i.e., NegP) also dominates the NP *anything*; in (37), Neg does **not** c-command the word *anything* because the first branching node above Neg (again NegP) does **not** dominate *anything*.

It may seem as if we are using a sledgehammer to crack a nut, but the beauty of the analysis is that c-command is not just an arbitrary condition introduced to account for a narrow range of data in English. Rather it extends in two directions: it is a major and essential ingredient in the explanation first of a range of other phenomena in English; and second to a wide range of phenomena in other languages, indeed in all languages: **c-command is universal**.

Before illustrating other uses of c-command, note that if it is universal, we would like an explanation for how that is possible. The obvious answer is that it is innate, part of the faculty of language that differentiates humans from other organisms and explains why all kids but no kittens acquire language. If correct, certain implications follow immediately: c-command is not a condition that children acquiring their first language need to learn, rather (like structure-dependence) it acts as a constraint that determines the kind of hypotheses they can come up with in mastering their first language.

Let us look at one generalization of the usefulness of c-command in English: its use in 'binding theory', the part of linguistics that deals with the distribution of pronouns and reflexives. It is a commonplace that reflexive pronouns such as *myself, yourself, himself,* and so on, have to agree (or 'be compatible') with their antecedent – the entity they refer back to, so the examples in (38) are fine, but those in (39) are ungrammatical:

(38a) I admire myself
(38b) The judge admires himself
(38c) The waitress might flatter herself

(39a) *I admire yourself
(39b) *He admires herself
(39c) *The waitress flattered ourselves

There are all sorts of other interesting complications with reflexives: if there are two possible antecedents, the sentence is ambiguous, so in (40) *herself* can refer to either *the nurse* or *the woman*:

(40) The nurse showed the woman some documents about herself

but this is true only if the two potential antecedents are in the same clause as the reflexive: (41) is unambiguous, and *herself* can refer only to *the princess*, because *the queen* is in a different clause:

(41) The queen said the princess had disgraced herself

Neither of these extra considerations accounts for why (42a) is unambiguous and (42b) is simply ungrammatical:

(42a) The mother of the princess has disgraced herself
(42b) *The brother of the princess has disgraced herself

The question is why *herself* in (42) can't refer back to *the princess*, but only to the *mother* or the *brother*, resulting in the judgements indicated. The answer is that the antecedent of the reflexive must not only be compatible and in the same clause, but must also c-command it. The structure of possessives such as *the princess's mother* or *the mother of the princess* is a matter of contention, but what is not in dispute is that *princess* is lower in the tree than *mother* or *brother* and hence does not c-command the reflexive: compare the trees in (43a) and (43b) for (38c) and (42a):

(43a)

(43b)

In both trees, the underlined DP (*The waitress* in (43a), *The brother/mother of the princess* in (43b)) c-commands *herself,* but the crossed-out DP *The princess* in (43b) does not c-command *herself* so cannot act as its antecedent.

C-command is pervasive in the syntax of English, not just in accounting for polarity items and reflexives. More strikingly, it is pervasive in the syntax of every other human language. Consider (Cantonese) Chinese. Cantonese has a rich selection of sentence-final particles with a wide range of meanings from conveying a feeling of intimacy to indicating which element in the preceding sequence is the focus. In English, we can indicate this focus by means of stress, giving rise to the kind of difference in (44a) and (44b):

(44a) John only **watches** football (he doesn't play it)
(44b) John only watches **football** (not cricket)

It's even possible, with suitable pause and stress, to have (45b) with the same interpretation as (45a):

(45a) Only **John** watches football (not Bill)
(45b) **John** only, watches football (not Bill)

Just as in English, Cantonese uses stress to identify the intended focus from the set of possible foci, and the operator *zaa3* (*only*) then associates with this intended focus, as in (46), which can have the various interpretations shown in (47):

(46) Billy tai zukkau zaa3
Billy watch football zaa3

(47a) Only **Billy** watches football (not Peter)
(47b) Billy only **watches** football (he doesn't play it)
(47c) Billy only watches **football** (not cricket)

There is good evidence (see Law, 2004) that *zaa3* occurs in some C position of the sentence, and hence c-commands everything preceding it in the example in (46): see the tree in (48), (C is arguably final in Cantonese, not initial as it is in English):

(48)

But to talk simply in terms of linear precedence or word order is inadequate. Cantonese also has a process of topicalization whereby a constituent – e.g., *zukkau* ('football') – can be moved to the front of the sentence, where it is attached even higher in the tree than *zaa3*, and marked with *le1* (the 1 indicates a high level tone). This is shown in (49a), with a range of putative translations in (49b) to (49d). Crucially, as indicated by #, (49d) is **not** a possible interpretation of the Cantonese sentence.

(49a) zukkau-le1, Billy tai t zaa3
(49b) Football, only Billy watches
(49c) Football, Billy only watches
(49d) #Only football does Billy watch

Why this should be so is indicated in the tree in (50), where *zukkau* is not c-commanded by *zaa3*: (The 't', for 'trace' in (48a) and (49a) indicates where the topicalized constituent *zukkau* moved from).

(50)

Because *zaa3* does not c-command *zukkau,* the attempted interpretation in (49d) is simply impossible. The examples are extremely simple, indeed extremely oversimplified, but the moral is clear: the same abstract syntactic condition (c-command)

operates in Chinese just as it does in English, and in every other language.

It is worth emphasizing that successful explanations for one class of data are good to the extent that they generalize to phenomena for which they were not devised. C-command was not invented to account for Chinese, but the fact that it automatically accommodates quite subtle data in that language lends support to a theory that incorporates it. The point can be illustrated more widely. Every time one draws a tree of the kind illustrated above, one makes predictions about the well-formedness of a host of other sentences. It is striking that the trees in (36) and (37) exhibit a defining property of human language – its recursive power. That is, the possibility of including one sentence inside another sentence, potentially without limit, gives rise to the infinite expressive power of natural language syntax.

Linguistics as a 'Science'

Making testable predictions of this kind is one of the hallmarks of science, and we can now elaborate on the claim that linguistics is 'scientific'. For any discipline to be scientific it must satisfy (at least) the conditions in (51):

(51a) It must seek **explanation**
(51b) It must pursue **universals**
(51c) This will necessarily involve **idealization** which may well give rise to a tension between commonsense and science
(51d) Most crucially, it will make **falsifiable predictions**

The scientific enterprise is a search for explanatory laws or principles. That is, linguists – like physicists or molecular biologist – seek not only data, but also data that can be used as **evidence** for some theoretical claim. Consider again the analysis of reflexives. Early work in linguistics of the sort best exemplified by the work of Bloomfield (1935) provided detailed exemplification of a wide range of reflexive constructions from a variety of languages, but stopped short of trying to explain their distribution. One of the achievements of generative grammar has been precisely to explain – in terms of 'binding theory' – why reflexive pronouns have the distribution they do. To elaborate a little on the discussion given already under the 'Explanation in Language' section, the appearance of a reflexive pronoun is determined by principle A of binding theory which says that a reflexive must be 'bound' in some domain. As we saw, this means that it must have an antecedent which also meets a number of other conditions. Principle A is in contrast with Principle B, which determines the distribution of 'ordinary' pronouns. That is, between them the principles account for the range of facts discussed above as well as for the contrast between *John admires him* and *John admires himself*; why one can construe *John* and *him* as referring to the same person in (52b) but not in (52a), even though the latter seems to include the former as a proper subpart, and a host of other facts:

(52a) John expects to see him
(52b) I wonder who John expects to see him

Evidence for – or against – the claims of binding theory, or any part of the theoretical edifice, can be drawn from a wide variety of domains: the distribution of words in sentences; the acquisition of their first language by children, and of second and subsequent languages by both children and adults; the historical change of language over time; the processing of language – be it production or perception – in normal and abnormal circumstances; the problems that arise in pathology, as a result of language disturbance caused by a stroke or a tumor, and so on. In every case, explanation calls for concentration on those data that can provide evidence: the data themselves are trivial until embedded in a theory that can produce testable hypotheses.

A concomitant of this search for explanation is that the generalizations made must carry over in relevant ways to all languages, not just to English or Latin or Chinese. That is, the quest for laws entails that any science must pursue *universals*, even if that means narrowing the domain of inquiry. This position has two implications: first, that the same principles should apply to Dutch and Hindi and Chinese – so 'all languages' is to be construed literally; but second, that the domain of application of these principles may not be superficially obvious. To take the second observation first, it is well-known that there are so-called 'emphatic' reflexives, as illustrated in (53a) and (53b), which raise difficulties for any simple analysis of reflexivization in general:

(53a) John himself came
(53b) John came himself

These 'reflexives', so labeled because they include the morpheme {*self*}, have somewhat different properties from 'real' reflexives: for instance, they don't have any thematic role, (*came* takes only one argument – you can't 'come somebody else'), but simply emphasize the importance of the one role mentioned. On the other hand, they clearly do obey some of the same constraints as ordinary reflexives, as witness the peculiarity of the examples in (54):

(54a) *The boy came herself

(54b) *The boy's mother himself came

This duality suggests that it might be necessary – as a temporary measure – to limit the domain of binding theory to arguments taking a thematic role, leaving the emphatic examples to be accommodated later after further research. The situation is parallel to the development of a scientific theory of motion. For Aristotle, all motion fell within the ambit of his theory of movement, even the movement of flowers growing. Galileo was able to provide a unified account of terrestrial and heavenly motion by restricting attention to mechanical motion and excluding biological growth. This should not be viewed as a retreat to a position where whatever you say turns out to be true, simply because you have excluded those areas where what you say is false. Rather it is an attempt to define an area where we can begin to understand the complexity of the real world by focusing on phenomena that are comprehensible.

This narrowing is of two kinds: first, one can simply ignore data which fall outside the generalization one is attempting to explain; second, there is scientific idealization – the pretence that things are simpler than they really are. This is justified because such simplification enables one to approach an understanding of the abstract principles which underlie complex phenomena. Such idealization in linguistics was first made explicit in Chomsky's distinction between competence and performance and his claim that "linguistic theory is concerned primarily with an ideal speaker-listener, in a completely homogeneous speech-community." We all know that real speech communities are not homogeneous, but the force of the idealization is that the heterogeneity that does exist is not a necessary component in an adequate characterization of our knowledge of language or how we come by that knowledge. Consider in this latter respect the simplifying assumption – the striking idealization – that first language acquisition is 'instantaneous'. It is obvious that children take a considerable time to master the intricacies of their first language. Given how complex the knowledge they end up with is, it may still be justifiable to talk of the surprising speed with which they reach this mastery, but it is **not** by any stretch of the imagination 'instantaneous'. So what is the force of the assumption? Consider the acquisition of negation.

Most, perhaps all, children go through a stage in which they produce negative sentences with the negative marker (*no* or *not* in English) in peripheral position in the sentence – i.e., first or last – as in (55a) and (55b), heard from two different two-year-olds:

(55a) No computer on
(55b) Computer on no

The context made it clear in each case that the force of the utterance was an order not to turn the computer on. Superficially, it looks as if the two children have different grammatical systems (though they were equally proficient at understanding adult instructions, suggesting that their grammar was more sophisticated than might appear). What is relevant here, however, is the fact that – as far as is known – both children will end up with the same grammatical knowledge of English negation. That is, the different stages they go through in their acquisition of the details of the grammar has no effect on the knowledge they end up with – their adult competence. This claim may, of course, be false. It might turn out that adults who uttered (55a) as children have different grammars from those who uttered (55b) as children. It's possible, but there is no evidence to that effect, and the idealization to instantaneity is accordingly justified. If one of the things we wish to explain is how humans can progress from a stage in which they are apparently language-less to a stage of adult knowledge, it is advantageous to be able to abstract away from the different paths they may take in acquiring that knowledge. The idealization also simplifies the account of the initial state of the language faculty: what needs to be attributed to the mental make-up of human infants to explain the fact that they do, while infant chimps do not, acquire language.

Idealization of this kind is in turn likely to involve a tension between commonsense and science. The claim of instantaneous language acquisition seems blatantly silly until one considers more carefully what it means. Consider a second example, again from first language acquisition. Children regularly mispronounce the words they are learning, sometimes with surprising results, as in the case of the puzzle puzzle. When he was about two and a half, my son – like many children – used to pronounce *puddle* as 'puggle' ([pʌgəl]). He was perfectly consistent, and used to pronounce words of a comparable kind with the same kind of deformation: so *bottle* became 'bockle', *pedal* became 'peggle', and so on. The obvious explanation for this behavior was that, for reasons of motor control, he was unable to pronounce *puddle*. But at the same time as he made this mispronunciation, he was also making 'mistakes' with words such as *zoo*, pronounced as 'do', *lazy*, pronounced as 'lady', and so on. The result was striking: although he pronounced *puddle* as 'puggle', he consistently pronounced *puzzle* as 'puddle' ([pʌdəl]), so the reason for the former 'mistake' could clearly not be that he was incapable of the appropriate motor control. He could pronounce 'puddle', but only as his version of *puzzle* not for *puddle*. So the commonsense explanation of the phenomenon was wrong. An

obvious alternative explanation was that he couldn't hear the difference, but that hypothesis wasn't much more plausible either, as his pronunciations of the two words were consistently different, indicating that he must be able to perceive the contrast. So the second 'obvious' commonsense explanation was equally problematic. The correct explanation was provided by Marcy Macken, who demonstrated that there was a perceptual problem, but not between *puzzle* and *puddle*, but rather between *puddle* and *puggle*. Of course, *puggle* is not a word of English, so I had failed to observe relevant examples. Words like *riddle* and *wriggle* provide a straightforward minimal pair, but they had not been in my son's vocabulary. Fortunately, Macken observed that other examples made the case as well as the (missing) minimal pair did. Words such as *pickle* were intermittently pronounced 'pittle' ([pit?l]) suggesting that there was indeed perceptual confusion. The puzzle puzzle could only be solved when the difference between a variety of other examples was simultaneously taken into account.

I have gone on about this example at such length because it illustrates the beauty of being (potentially) wrong. The most crucial part of the scientific enterprise is that it makes testable (or 'refutable' or 'falsifiable') predictions. Because my son regularly distinguished *puddle* and *puzzle*, and similar examples, I had claimed explicitly that he had no perceptual problem. Macken showed that I was wrong and, on the basis of my own data, showed how I was wrong, leading to an improvement in our general understanding of language acquisition, and the language faculty more generally. Such falsifiability is pervasive in linguistics as in all the sciences, and suggests that many, perhaps all, our hypotheses and principles will be in need of revision when we get a better understanding of what is going on. It follows that binding theory, which I have appealed to above, is probably wrong, and will need replacing by some more sophisticated theory in due course. Again this is to be welcomed, though we must simultaneously guard against the danger of 'naive falsificationism'. There are always going to be contrary data that one's current theory cannot explain. This is not a reason for simply jettisoning the theory and whatever insights it may provide, but a point of departure for refinement and extension. A clear example is provided by the theory of parametric variation, and the striking revision of his earlier work in Chomsky's current Minimalist Program (1995).

I have suggested that, like all principles of grammar, binding theory should be universal. But there are problems. Even though (virtually) all languages have reflexives, their distribution is subject to slightly different conditions in different languages. Consider again the contrast between (40), *The nurse showed the woman some documents about herself,* and (41), *The queen said the princess had disgraced herself*, where the former is ambiguous but the latter is unambiguous. The contrast was attributed to the fact that (in English) the antecedent of a reflexive must be in the same clause. So far so good, but if one takes equivalent examples in Chinese, it turns out that the equivalent of (40) is unambiguous, and the equivalent of (41) is ambiguous. The theory would appear to have been refuted: a prediction was made, it was tested, and found to be false. But simply giving up the theory would be defeatist, and it would also mean giving up the explanation for the data it does account for.

The solution is interesting: the universality of binding theory (and likewise for other subtheories of the grammar) is maintained, but some latitude is allowed in the definitions involved – they are 'parametrized', as the jargon has it. In this case, all reflexives have to have an antecedent, but language learners have to choose (on the basis of the data they are exposed to) among several other options: whether they are learning a language in which that antecedent has to appear in the same clause or in some other well-defined domain; whether the antecedent has to be a subject or can bear other grammatical relations, and others. In Chinese, the antecedent of a reflexive must be a subject, so (40) is unambiguous; on the other hand, that antecedent does not have to be in the same clause, so (41) is ambiguous. If you are worried that this is too simple a get-out, an analogy with incest may be helpful: all cultures appear to have an incest taboo forbidding sexual relations between relatives (for instance, fathers and their daughters). The taboo is universal. But how that taboo is instantiated is culture-specific: for example, some groups allow cousins to marry, others do not. The situation with regard to language and language-learning is somewhat more complex than the cultural example, because there are many more choices to be made. The acquisitional task is more complex than it would have been if all languages were exactly like English, but it is not as severe as one might fear. The idea is that the full range of parametric choices in language is available to the child prior to experience – they are in some sense innate – and the child's task reduces to choosing from a set of language structures options it already 'knows.'

Beyond Language: Pragmatics and the Language of Thought

We have looked at a wide range of examples illustrating some of our knowledge of phonology, morphology, semantics, and (mainly) syntax, but we also have

knowledge that goes beyond words and sentences. Consider (56a) and (56b): as a remark about Fred, (56a) is fine, with stress on *bats* as indicated by the bold print, but as a reply to the question in (56b) it is anomalous:

(56a) Fred has written a book about **bats**
(56b) Who has written a book about bats?

Such discoursal knowledge must be distinguished both from syntactic knowledge of the kind that tells us that (57) is ungrammatical:

(57) Fred has written about **bats** a book

and from real world knowledge of the kind that prompts our scepticism about (58a) and (58b):

(58a) Bananas have legs
(58b) Your saucer is being aggressive again

Someone who utters (56a) in response to (56b) probably needs remedial English lessons; someone who utters either of the sentences (58a) or (58b) is either a linguist or in need of psychiatric help.

This brings us into the realm of pragmatics, our interpretation of utterances in context, and to the relation of language to thought. The examples in (58a) and (58b) are felt to be odd not because of our linguistic knowledge – you get the same effect whatever language you translate them into – but because we know that the world isn't like that. It is our encyclopedic knowledge that tells us this, not knowledge of our language (English). However, when we interpret someone's utterances in some context, we habitually use both our knowledge of English (or whatever other language we are using) and our encyclopedic knowledge. Suppose you hear (3a) *Tom is a problem*. Your knowledge of English vocabulary and grammar provides you with a meaning for the sentence, but it doesn't tell you enough to act. Is your interlocutor looking for sympathy, asking you to do something about it, hoping for a denial? Any or all of these may be what you decide is the case on a particular occasion, but you carry out this construal on the basis of your knowledge of the speaker, of Tom, of your past exchanges with both of them, and so on, indefinitely. The core notion involved is what is 'relevant', an idea that has been made explicit in Relevance Theory, an important extension of linguistics. We are now beyond the language faculty and can hand over responsibility to other disciplines; but one final question needs to be addressed: What is language for?

There are two standard answers: for thought and for communication. Both answers are true, but both need a little hedging. First, we can obviously communicate without using language by means of coughs, sniffs, gestures, and so on. But language is far more subtle than any other system known: conveying specific negative or conditional propositions by means of gestures or sniffing is not obviously possible. Innumerable other creatures have complex communication systems, but none of them, as far as we know, have anything with the recursive power of human syntax (see Sperber and Wilson, 1995; Hauser *et al.*, 2002). Second, the system we use to think with must have a great deal in common with the natural languages we speak, but it is not identical to them. The language of thought can include elements that natural languages cannot – visual images, for instance; and natural languages have properties that would be unnecessary, or even unhelpful, in the language of thought – pronouns, for instance. If I tell you that *she is beautiful*, it's of no use to you storing that in memory as 'she' is beautiful; it has to be stored with a name or some other description replacing *she*. Nonetheless, language has a central role in each of these domains, linking perception and articulation on the one hand to thought processes on the other. This means that the output of our language faculty must be 'legible' to these other systems. Language acts as a code linking representations of sound to representations of meaning. These representations must then be in a form that makes it possible for the sensorimotor apparatus to convert them into pronunciations and percepts, and for the conceptual system to use them for thinking, especially inference.

So, linguistics provides an account of each of syntax, phonology, morphology, and semantics, and how they relate to each other; pragmatics then tells us how such purely linguistic representations relate to the language of thought – the medium in which we think and carry out inferencing. This relation underlies our ability to interpret the world and the people in it, but the linguistic component is only the first step on the journey. We normally take someone who utters 'torture is immoral' to *believe* that torture is immoral, and we expect to be able to predict (at least some of) their actions on the basis of this. But people may lie, and about that linguistics has nothing to say.

History of Linguistics in Central and South America

O Zwartjes, Universiteit van Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Spanish and Portuguese missionaries dedicated themselves to the study of non-Indo-European languages, resulting in the publication of a great number of works in or about the Amerindian languages. Although missionaries based and structured their works in agreement with the traditional Greco-Latin grammatical framework, they were forced by the linguistic facts to search for unconventional solutions in their descriptions, which never had been studied before in Europe. There is no doubt that their approaches were in many cases original and creative on all subdisciplines of grammar: phonology; orthography (the rendering of sounds never heard or written before); morphology–morphosyntax (their model predated ours, not yet elaborated, used to describe phenomena such as agglutination, incorporation, different word structure, processes of derivation, and composition in typologically different languages); syntax (e.g., topicalization, ergativity, different word order, the dichotomy active and nonactive, incorporation); and lexicography – another challenge for the missionaries and an important tool for the translation of religious texts.

Missionary works are important sources for other subdisciplines of linguistics, such as sociolinguistics (language variety, language change, standardization), pragmatics, translation theories, cultural anthropology; for reasons of space these will not be treated in this article. Descriptive linguistics always requires an underlying theoretical framework and reflects the linguistic thinking of the period in question. Interest in

whereby modifiers are always located on the same side of the head. Bybee (1988) argues, however, that the correlation is actually motivated in diachronic terms: adpositional constructions typically originate from genitival constructions, and they maintain the order of genitival constructions. In this case, Bybee argues, functional principles may be invoked to account for why adpositional constructions develop from genitival constructions in the first place, but no functional principle can actually be invoked to account for the word order correlations between the two constructions.

It should finally be observed that a widespread assumption in the typological approach is that the various language types allowed by implicational universals reflect different functional principles, and the competition between the various functional principles determines cross-linguistic variation (Du Bois, 1985). For example, an implicational pattern exists such that if the singular is expressed by a certain number of morphemes, then the plural will be expressed by at least as many morphemes. This is usually explained in terms of an economic principle, whereby the singular is the most frequent category at the discourse level and therefore need not be expressed overtly. One such explanation accounts for the existence of languages in which the singular is zero-marked and the plural is marked overtly. However, the implicational pattern also allows for languages in which both singular and plural are expressed overtly. These languages reflect an iconic principle whereby all aspects of conceptual structure (in this case, the values 'singular' and 'plural') are expressed overtly (Croft, 2003). The implicational pattern allows for both language types, but the two language types reflect competing functional principles, each prevailing in different languages. The competition between the different principles is what determines cross-linguistic variation, as described by the implicational pattern itself.

Linguistics as a Science

B Clark, Middlesex University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

A common description of linguistics is that it is the 'scientific study of language.' This might seem to be a loose or metaphorical use since the subject matter of linguistics is quite different from what are often thought of as the 'hard' sciences such as physics or chemistry. But linguists are engaged in a process of inquiry that aims to discover facts about the world we live in, and so their work shares important properties of other sciences. Some work in linguistics (e.g., acoustic phonetics) resembles the 'hard' sciences in

that it studies physical phenomena in the world. Like psychology, linguistics faces specific issues associated with the fact that its subject matter involves properties of humans, namely, linguistic knowledge and behavior. This article considers some views on what it means to say that a discipline is scientific, what it means to investigate language scientifically, and some different scientific approaches adopted by linguists.

What Is a Science?

The general, popular assumption about what constitutes a science is still probably one based on 'inductivism,' or logical positivism, which was the dominant view of science at the start of the 20th century. In this view, scientists must begin by making sure that they are as objective as possible and simply observe relevant data without prejudging it. They must also make every effort to ensure that they do not themselves affect the data that they are studying. After objectively observing the data, generalizations will emerge and from these generalizations, laws can be derived.

Suppose, for example, that we go to the Antarctic and observe penguins. After a certain number of observations, we might notice that we have never seen a penguin fly. On the other hand, we have seen many penguins swim. So we wonder whether these facts might be the basis of generalizations. We continue to observe and every penguin we observe swims but none of them fly, so we do generalize and come up with the hypotheses that:

(1) No penguins can fly
(2) All penguins can swim

These hypotheses can then be tested by further observation. We might also devise specific tests. For example, we might encourage penguins into the air to see whether any of them attempt to fly. Or we might put penguins in water to make sure each of them can swim. Hypotheses (1) and (2) will hold as long as every penguin we observe swims but fails to fly. If repeated tests confirm the hypotheses, then they will be established as verified conclusions.

This approach seems intuitive and clear to most people, but there are serious problems with it. Adapting a diagram from Chalmers (1999: 54), we can represent this way of approaching science as in Figure 1.

Figure 1 Inductivist model of science (based on Chalmers, 1999: 54).

Perhaps the most fundamental problem with this model is that the derivation of laws and theories is based on induction, which means that they can never be guaranteed to be true. To see this, we need to look at what is involved in induction.

Induction is a process whereby general conclusions are derived based on evidence provided by specific observations in the past. If I go to the same bar often enough and order the same drink, say, a pint of stout, every time, it is possible that the bartender will conclude that I will want a pint of stout every time I come into the bar. If he is keen to make sure I am happy, he might even start pouring my stout as soon as he sees me arrive.

The problem, of course, is that there is nothing to stop me deciding one day to have something different for a change. If I do order a different drink one day, say a glass of lemonade, then the bartender will have wasted his time, and possibly his stout. In other words, conclusions that have been derived through a process of induction are not secure. By contrast, deductive conclusions are guaranteed to be true as long as the premises on which they are based are true. Here are possible steps in the bartender's inductive reasoning process:

(3a) Billy ordered a pint of stout when he came into the bar on Monday.
(3b) Billy ordered a pint of stout when he came into the bar on Tuesday.
(3c) Billy ordered a pint of stout when he came into the bar on Wednesday.
(3d) Therefore, Billy will order a pint of stout every time he comes into the bar.

And here are two examples of deductive inferences:

(4a) Billy will order a pint of stout every time he comes into the bar.
(4b) Therefore, Billy will order a pint of stout when he comes into the bar on Thursday.

(5a) Billy is drinking stout
(5b) All stouts are alcoholic drinks.
(5c) Therefore, Billy is drinking an alcoholic drink.

While (3a–c) could be true and (3d) still turn out to be false, there is no way that (4a) could be true and (4b) false, or that (5a–b) could be true and (5c) false.

The unreliability of inductive inferences is a serious problem for the inductivist approach to science, since it means that no conclusion can ever be safely asserted to be true. You never know for sure that the next penguin you look at won't be able to fly, or whether the next penguin you look at will indeed be able to swim. This means not only that we can't be sure of

our conclusions but also that we can never be sure that our scientific endeavors have resulted in any progress. It is always possible that we have just moved from one false hypothesis to another, since we have not been lucky enough to come across the data that would demonstrate our mistake.

Another problem with this view of scientific inquiry is that it is not possible to observe phenomena objectively without first making some assumptions about what might be relevant. Suppose, for example, that I decide I am interested in how children acquire their first language. How will I know which things to observe? Should I begin by observing the speech of the children themselves? Or the speech of other children around them? Or the speech of grownups around them? Or other kinds of behavior exhibited by the children themselves? Or other kinds of behavior exhibited by other children? Or other kinds of behavior exhibited by grownups around them? Or the extent to which they see or hear television? Or their diet? There are countless possibilities and we cannot begin carefully observing data without first guessing which particular data might be relevant. In the same way, hypotheses about whether penguins can fly or swim arise because someone asks the question whether they can. A scientist following the inductivist model might just as easily have decided to look at the penguins' color, their physical behavior, how they mate, how many of them are ever together in one group, and so on. The hypotheses about their status as flightless swimmers will only arise if it is assumed that it might be relevant in this context. Not only does the inductivist model of science mean we can never be sure we've made any progress, we also don't have any clear rationale for deciding on our first steps in investigating a particular phenomenon.

These were acknowledged problems for the traditional, inductivist model of science. But no superior model was available until the philosopher Karl Popper (1972, 1979) suggested a new way of thinking about science. He pointed out that, even though we can never be sure an assumption is true, we can demonstrate a conclusion to be false. If I order a glass of lemonade even once, then we know that it's not true that I only ever order stout. If we see just one penguin that can fly, then we know for certain that not all penguins are flightless. He pointed out that falsifying a hypothesis counts as progress, not only because it removes an error from a theory but also because it usually leads to a new, improved hypothesis. Suppose, for example, that we discover a flying penguin. We will not simply reject our initial hypothesis that all penguins are flightless and start again from scratch. Instead, we will wonder what the difference is between those penguins that fly and those

Figure 2 Popperian (falsificationist) model of science.

that don't. We might, for example, discover that there is a particular penguin species that can fly and come up with a new hypothesis to reflect that.

Another important point Popper made was that the source of hypotheses is much less important than whether they make clear predictions and so can be tested to see if they are false. Newton's theory of gravity, for example, clearly predicts that any object we drop will fall towards the earth. Other things being equal, we know that a floating or rising object will demonstrate that the hypothesis is false. By contrast, if your horoscope claims that 'someone is thinking of you,' it is clearly impossible to show that this is not so. Therefore, this is not a falsifiable, and so not a scientific, claim.

Popper's approach suggests that observation does not need to be the first step in a process of scientific inquiry. Instead, hypotheses can, and indeed must, precede observation. Hypotheses may arise because of objective observation, because of some subjective prejudice, because we dream them, or from any source at all. What is important is that we can test them and so attempt to make progress in our understanding. Popper's view of how science progresses can be represented diagrammatically, as in Figure 2.

The foundations of science, in this view, are not based on objectivity and the notion that observation precedes hypothesis formulation. Instead, what is important is that our hypotheses are clearly formulated and testable. Since we can never verify a hypothesis, we aim instead to develop the best hypotheses we can, and this is evaluated in terms of clarity and falsifiability. Because of the prominence it gives to hypothesis formation and to deductive inferences, Popper's vision of science is also known as the 'hypothetico-deductive' model.

Naturally, there are a number of alternative visions. Imre Lakatos (1970) developed a more sophisticated falsificationist model based on considering the nature of scientific research programs rather than isolated hypotheses, or sets of hypotheses. Thomas Kuhn (1970) suggested a sociological model, in which he described science in terms of paradigms. In Kuhn's view, a scientist proceeds first by learning a current paradigm. He then solves 'puzzles' using the tools available within the paradigm. Sometimes, puzzles are not solvable within the existing paradigm. If this continues, a crisis occurs that eventually leads to

a 'revolution' in which the existing paradigm is discarded and a new paradigm takes its place. One important feature of Kuhn's approach is that its sociological nature means that it does not provide a means of distinguishing between scientific and non-scientific statements other than in terms of what is accepted by the relevant group of scientists. A more radical position is taken by Paul Feyerabend (1975, 1978), who claims that the notion of a reliable scientific methodology is an illusion and that scientists have failed to demonstrate that their findings have more value than any other kinds of 'wisdom.'

Whichever philosophy of science is assumed, work in linguistics fits the model as well as any other science. Linguists do not all agree about the nature of their scientific endeavor, but the majority of linguists do see linguistics as a science; and Popper's views on what constitutes scientific activity have been influential in linguistics, just as they have been in other disciplines. (For an introduction to the philosophy of science, see Chalmers, 1999).

The Scientific Study of Language

As Yngve points out, "the origins of linguistic theory can be recognized in Plato and Aristotle, but most clearly in the early Stoics from about 300 to 150 B.C.' (Yngve, 1996: 14). Modern **scientific** linguistics began to develop in the early 19th century in the work of scholars such as Rasmus Rask, Jacob Grimm, Franz Bopp, and Wilhelm von Humboldt. Rask (1830) referred to Linnaeus and Newton in proposing that language was a natural object that should be studied scientifically. The main focus at this time was on the comparative method, looking at similarities among different languages and using this evidence to reconstruct the ancestors of languages. (For a fuller account of the history of linguistics, see Robins, 1990.) The notion that linguistics is a science has continued since then, while assumptions about what makes linguistics scientific have changed. Perhaps the most significant developments have been the work of Ferdinand de Saussure (1972, 1983), which is usually seen as the starting point of modern linguistics; the development of a rigorous notion of linguistics as a science by Leonard Bloomfield (1926, 1933, 1970) and his American contemporaries in the first half of the 20th century; and the overturning of Bloomfield's approach by the work of Noam Chomsky (1957, 1965). In linguistics today, there are a wide range of approaches, methodologies, and notions of what is scientific, but the Chomskyan approach remains the dominant one.

Saussure's ideas established the notion that linguistics could be 'synchronic' (concerned with a particular language at a particular point in time) as well as 'diachronic' (looking at how a language has developed over time). Saussure's work had considerable influence in the development of structuralist approaches in linguistics and beyond. One particularly significant structuralist approach was that of Bloomfield and his followers in the first half of the 20th century, who developed a much more detailed view of linguistics as a science. As Robins (1990: 208) puts it, "Bloomfield was rigorously scientific, in the light of his own, mechanist, interpretation of science, concentrating on methodology and on formal analysis." It was important for Bloomfield that linguistics should be seen as a scientific enterprise, and his view of what it meant to be scientific was an empiricist one, based on behaviorist psychology. A scientific approach was an empirical study based on objective observation of facts that would lead the scientist to discover facts about languages. It was vital to avoid subjectivity. This meant avoiding hypotheses that did not emerge from objective observation, and it also meant denying the existence of the mind or of mental phenomena. This was because the data alone, considered objectively, did not justify the assumption that mental phenomena really existed. For behaviorists, all behavior could be explained in terms of external stimuli and the reflexes that they caused. Even very complex behavior, such as linguistic behavior, could be understood in terms of complex responses to stimuli. Perhaps the main concern of linguistics was to record facts about particular languages. This was given urgency by the fact that many native American languages were threatened with extinction. It was important that they should be recorded before they were lost forever. Linguists developed a number of 'discovery procedures' that could be used to scientifically (i.e., objectively) work out facts about the languages being studied.

Chomsky's approach explicitly rejected at least the following assumptions of the Bloomfieldian approach:

- That observation should precede hypotheses
- That the ultimate aim of linguistics was to describe
- That languages were to be understood as collections of utterances (phenomena external to the mind)
- That linguistics should not presuppose the existence of mental phenomena.

Chomsky argued instead that:

- The main aim of linguistics was to construct theories of language and languages
- The ultimate aim of linguistics was to explain language and languages

- That language should be understood as a mental phenomenon (and languages as mental phenomena)
- That there was strong evidence for the existence of the human mind and a cognitive system of knowledge of language.

In general, the key notion in Chomsky's work was that there was convincing evidence for the existence of mental structures underlying human language. This evidence came from the linguistic intuitions of speakers. These included intuitions about what is and is not possible in languages they know. A famous example is the contrast between *eager to please* and *easy to please* illustrated in (6)–(7):

(6a) John is easy to please
(6b) It is easy to please John

(7a) John is eager to please
(7b) *It is eager to please John

(The asterisk is used here to indicate that most speakers judge (7b) to be unacceptable. It is also used sometimes to indicate the theoretical claim that (7b) is not grammatical in English).

Speakers of English agree that (6a) and (6b) are both acceptable and have similar meanings. Although there is no logical reason for ruling out (7b) and it is easy to see what it would mean by analogy to (6a), speakers agree that (7b) is not an acceptable utterance. This can be explained by the assumption that a cognitive system of knowledge, a grammar, licenses (6a), (6b), and (7a) but rules out (7b).

Using examples like this, Chomsky argued for the existence of mental grammars ('competence') that underlay actual human linguistic behavior ('performance'). In Chomsky's (1986: 15–51) terms, linguistics should move from the study of 'E-language,' or 'externalized language,' to the study of 'I-language,' or 'internalized language.' This approach revolutionized linguistics, was a major influence on the so-called 'cognitive revolution' that reestablished the mind as a focus of study in psychology, and led to the establishment of the discipline of cognitive science. So what is the scientific methodology of Chomskyan linguistics like? To a large extent, it follows the Popperian model represented in **Figure 2**.

The focus of linguistics is very much on coming up with clearly stated, testable hypotheses, testing them, and constantly updating hypotheses based on how they respond to testing.

However, things are not as straightforward as this. It is not always the case that we have a theory that copes with all of the data until we come across problematic data and we then replace that theory with a new theory. Instead, we compare theories and stick with the theory that we think is the 'best so far' in that it copes best with the relevant data. Most theories do not deal with all of the existing data, and we are usually aware of problems with some data. When this happens, linguists do not reject the theory that cannot cope with the difficult data. Rather, they note the difficulty and continue with their research program until they either find a way to deal with it within the existing theory or until a new theory is formulated that deals with this data and is preferable to the existing theory when looked at overall.

In some cases, data is difficult to interpret. It may be, for example, that speakers are divided over whether a particular form is acceptable. This may correlate with nonlinguistic facts about the group of subjects, such as age (e.g., speakers over a certain age make one judgment while younger speakers make another), class, gender, or geographical location. If so, then the variation in the data can be explained based on these correlations, e.g., as a dialect difference or as a difference in the language of different age groups (which could be an example of a language change in progress). In some cases, though, there may be no obvious correlation with nonlinguistic features of the subjects, i.e., the numbers of speakers who make the different assumptions about the status of a particular form might be comparable in all groups, whether divided by age, class, gender, or geography. When this happens, linguists may 'let the grammar decide'; in other words, they may decide that whatever their existing grammatical theory predicts about the form in question is correct.

In evaluating theories, Chomsky (1986, 2000) has proposed that we can consider three 'levels of adequacy' that our theories should aim to meet: observational, descriptive, and explanatory adequacy. A theory is observationally adequate if it describes correctly which forms are grammatical. It is descriptively adequate if it also characterizes knowledge that speakers have about those forms. It is explanatorily adequate if it provides an explanation for why the intuitions of speakers are as they are.

It is important to note that, in the Chomskyan view, a linguist's grammar is a theory about the competence of one or more speakers. So to say that a particular expression is 'grammatical' is to make a theoretical claim about the unconscious system of knowledge that speakers have about their language. This is one reason why linguists need to be careful when asking speakers for their judgments on particular utterances. Asking whether a particular form is grammatical may lead to confusion or may generate responses that reflect nonlinguistic (or metalinguistic) assumptions about the relative social status of different forms. So it is often better to ask questions like "Does this sound

like a likely utterance to you?" or "Could you imagine someone saying this?"

All sciences involve idealisations. A physicist studying the effects of gravity, for example, wants to observe what a feather and a ball would do if dropped in identical atmospheres and if they were not shaped in such a way that the feather is affected to a greater extent by air resistance than the ball. Similarly, Chomsky points out that the object of study for linguistics is an idealized linguistic system:

> Linguistic theory is concerned primarily with an ideal speaker-listener, in a completely homogeneous speech-community, who knows its language perfectly and is unaffected by such grammatically irrelevant conditions as memory limitations, distractions, shifts of attention and interest, and errors (random or characteristic) in applying his knowledge of the language in actual performance. (Chomsky, 1965: 3)

This quote has sometimes been misunderstood. Chomsky is not claiming that such a speaker-listener exists. Instead he is saying that linguistics is not concerned with those nonlinguistic properties that lead to different individuals performing differently when making judgments about their language or using it (i.e., with 'performance'). So linguists are studying an object that does not exist as a physical entity. No two speakers share exactly the same language, since all speakers have acquired their language in slightly different circumstances. However, the scientific study of language requires that we abstract away from the differences to find out about the underlying language faculty. This raises a number of methodological issues. Chomsky (1980: 189–192) makes an analogy between investigation of human language and investigation of thermonuclear reactions taking place inside the sun. It is not possible to set up a laboratory inside the sun and look directly at what is there. Similarly, we cannot view linguistic competence directly. However, we can observe light and heat emanating from the sun and make inferences based on this evidence about what is happening inside the center of the sun. Similarly, we can look at the performance of speakers of a language, including their 'metalinguistic performance' (Birdsong, 1989; Schütze, 1996), when asked to make judgments and make inferences about the system of competence that is involved in determining that performance.

In the Popperian spirit, linguistics should make no assumptions in advance about which data will be relevant in studying language, nor about what methods should be used in studying it. What is important is that hypotheses are clearly stated, testable, and tested. In practice, though, there has also always been a tendency for particular linguists to continue to use the same kinds of methods and data, so that certain groups are referred to in those terms, e.g., as 'corpus linguists' or 'intuitionists.' Much of the work of Chomsky and his followers has been based on evidence from the intuitions of speakers, gathered by personal introspection (i.e., the researcher's own intuitions) interview or questionnaire. But there is no reason in advance to rule out the relevance of other data, whether from corpora, psycholinguistic experiments, or other sources. There are constant debates about the reliability of particular kinds of data and methods for acquiring and interpreting it. Corpus data has been judged problematic because the precise data depends on the accident of who says or writes what at a particular time. Unusual but relevant data is unlikely to appear. The use of intuitions has been questioned because of the risk of subjectivity and the dependence on researchers gathering and interpreting them with enough care. And so on. But the vital thing is that the relevance of particular data is explicitly discussed and justified. As with all sciences, linguists will choose to pay particular attention to some data and to ignore other data based on the hypotheses they have adopted about what will be relevant. But the important question should always be whether the data can be shown to shed light on the particular hypothesis being investigated.

Not all linguists are theoretical linguists. Descriptive linguists aim only to describe languages, not to explain them. A descriptive grammar will aim to make clear what forms exist in a particular language. Any descriptive grammar will have to make idealisations since, as mentioned above, it is not clear that any two speakers will ever have internalized exactly the same system. Where a large percentage of a language group agree on a particular form, it is fairly easy for the descriptive linguist to write a grammar in agreement with the majority view. In other cases, it may be much harder to decide which option to adopt. The Bloomfieldian American Structuralists who preceded Chomsky were mainly concerned with describing languages. They developed efficient methods for determining facts about languages and provided a wealth of data that theoretical linguists can use in testing their hypotheses. Descriptive linguistics continues to provide useful data with a range of practical as well as theoretical applications.

Not all linguists use falsificationist, or 'hypothetico-deductive,' methods. Conversation analysts, for example, avoid idealisations and use inductive methods to arrive at their conclusions. Conversation analysis has its foundations in ethnomethodology, a branch of sociology that grew out of dissatisfaction with the methods of sociology in the 1960s and 1970s. Research in conversation analysis is qualitative rather

than quantitative and avoids early hypothesis formation. One rationale for this is that conversation is complex behavior, and explanations of it will presuppose an understanding of that complexity that cannot be justified until we find out more about the detail of what goes on in conversations. Harvey Sacks (1995), one of the originators of conversation analysis, explicitly states that he views his work as behaviorist and that this approach has much in common with the behaviorist methodology adopted by Bloomfield and the American Structuralists in the early 20th century.

One motivation for using inductivist methods is when research is qualitative rather than quantitative. Lazaraton (2002: 33) suggests that the following features can be seen to distinguish qualitative and quantitative research:

Qualitative Research	**Quantitative Research**
naturalistic	controlled
observational	experimental
subjective	objective
descriptive	inferential
process-oriented	outcome-oriented
valid	reliable
holistic	particularistic
ungeneralizable single case analysis	generalizable aggregate analysis

(Lazaraton, 2002: 33)

Qualitative research is appropriate when the aim is to discover the attitudes and experiences of speakers and the motivations and processes behind events, rather than simply counting the number of times a particular event occurs. This is not to suggest that there is a necessary link between particular types of research (e.g., quantitative or qualitative) and particular models of science (e.g., inductivist or falsificationist); neither quantitative nor qualitative research are necessarily incompatible with any particular model of science.

Not everyone agrees that linguistics is an empirical science. Some reasons for this view stem from the use of intuitions as data. Itkonen (1974), for example, suggested that the reliance on intuitions means that the claims of linguists cannot be falsified. He suggests that the occurrence of an utterance such as **girl the came in* does not falsify the claim that definite articles in English precede nouns in a noun phrase, since this utterance is 'incorrect' and the claim is about 'correct' utterances and sentences. Given this, he suggests that linguistics is different from natural sciences, in which, for example, the discovery of a piece of metal that does not expand when heated would be enough to falsify the claim that all metals expand when heated. Yngve (1996) suggests that the 'ancient semiotic-grammatical foundations' of linguistics are not compatible with modern science. As a result, he suggests putting these foundations aside and replacing them with "new foundations that are fully consonant with modern science as practiced in the more highly developed sciences of physics, chemistry and biology" (Yngve, 1996: 309). Yngve's proposal can be seen as an attempt to reconceptualize linguistics as a 'hard' science. This raises the questions of whether all of the phenomena that have been studied by linguists can fit into this new model and whether the discipline retains its interest if they do not.

For most linguists, however, linguistics is by definition scientific. While much work in linguistics can be understood in some form of Popperian, or post-Popperian, terms, there is nevertheless a wide range of views on the exact nature of the scientific study involved.

Linguistics as a University Subject: Early History, in America

J S Falk, La Jolla, CA, USA

In the 1860s, William Dwight Whitney (1827–1894), professor of Sanskrit and instructor of modern languages at Yale College, became increasingly concerned that students in American higher education were beginning work in comparative philology without an understanding of 'the grand truths and principles which underlie and give significance to their work' (Whitney, 1867: viii). Whitney then wrote the book that became the most important linguistics text in 19th-century America, *Language and the study of language: twelve lectures on the principles of linguistic science* (1867). Many of his idea's on the nature of human language remain central to modern linguistics – the primacy of speech over writing, the arbitrary connection between sound and meaning, the universality and ease of language acquisition by children. But the central topics of 19th-century German linguistics – genetic and typological classification and the causes of language change – formed the core of his text and of the graduate program in philology that he established at Yale in 1869, one of the earliest graduate programs in any field in the United States.

At the turn of the 19th to the 20th century, Franz Boas (1858–1942) held one of the few professorships in anthropology in all of North America, at Columbia University in New York City. Boas considered linguistic study of Native American languages to be one of the core curricular areas for graduate studies in anthropology. He used his own field notes from languages on the Northwest Coast to demonstrate linguistic analysis in the classroom, and following experience there, students specializing in linguistics conducted work in the field. The *Handbook of American Indian Languages* (Boas, 1911) provided both the model of linguistic analysis to be followed in dissertations and their chief venue of publication.

Largely synchronic and focused on Native American languages, the path of Boasian linguistic education was different from that of the historical studies fostered by Whitney within the German historical paradigm. Under Whitney, students sought a foundation in classical languages, in older forms of modern languages, and, for research purposes, in the European languages of scholarship, along with such general knowledge of language as was provided in Whitney's textbook. They were then equipped for historical linguistic work. Under Boas, there were courses in ethnography, in physical anthropology, in statistics, and courses demonstrating the analysis of American Indian languages, which prepared students for independent field work and linguistic analysis.

No matter which of these traditions was emphasized in the early decades of the 20th century, there were no autonomous university departments of linguistics. Rather, the few linguistics programs that came into existence were assembled from faculty already appointed in other departments. For example, when Yale University announced a new department of linguistics in 1931, the only person to hold the title of professor of linguistics was Edgar H. Sturtevant

In the 1860s, William Dwight Whitney (1827–1894), professor of Sanskrit and instructor of modern languages at Yale College, became increasingly concerned that students in American higher education were beginning work in comparative philology without an understanding of 'the grand truths and principles which underlie and give significance to their work' (Whitney, 1867: viii). Whitney then wrote the book that became the most important linguistics text in 19th-century America, *Language and the study of language: twelve lectures on the principles of linguistic science* (1867). Many of his idea's on the nature of human language remain central to modern linguistics – the primacy of speech over writing, the arbitrary connection between sound and meaning, the universality and ease of language acquisition by children. But the central topics of 19th-century German linguistics – genetic and typological classification and the causes of language change – formed the core of his text and of the graduate program in philology that he established at Yale in 1869, one of the earliest graduate programs in any field in the United States.

At the turn of the 19th to the 20th century, Franz Boas (1858–1942) held one of the few professorships in anthropology in all of North America, at Columbia University in New York City. Boas considered linguistic study of Native American languages to be one of the core curricular areas for graduate studies in anthropology. He used his own field notes from languages on the Northwest Coast to demonstrate linguistic analysis in the classroom, and following experience there, students specializing in linguistics conducted work in the field. The *Handbook of American Indian Languages* (Boas, 1911) provided both the model of linguistic analysis to be followed in dissertations and their chief venue of publication.

Largely synchronic and focused on Native American languages, the path of Boasian linguistic education was different from that of the historical studies fostered by Whitney within the German historical paradigm. Under Whitney, students sought a foundation in classical languages, in older forms of modern languages, and, for research purposes, in the European languages of scholarship, along with such general knowledge of language as was provided in Whitney's textbook. They were then equipped for historical linguistic work. Under Boas, there were courses in ethnography, in physical anthropology, in statistics, and courses demonstrating the analysis of American Indian languages, which prepared students for independent field work and linguistic analysis.

No matter which of these traditions was emphasized in the early decades of the 20th century, there were no autonomous university departments of linguistics. Rather, the few linguistics programs that came into existence were assembled from faculty already appointed in other departments. For example, when Yale University announced a new department of linguistics in 1931, the only person to hold the title of professor of linguistics was Edgar H. Sturtevant

(1875–1952). He and all other faculty were jointly appointed with other departments, including anthropology, classical languages and literatures, English, Germanics, and Semitic and Biblical languages and literatures. Yale initially offered only the Ph.D. in linguistics; a Master's degree became available in 1943–1944. Instruction remained entirely at the graduate level, a pattern for most linguistics programs until the later decades of the 20th century. Yale did not teach an undergraduate linguistics course until 1947–1948 and did not grant its first undergraduate degree in linguistics until late in the 1960s (Wells, c. 1975: 18 n. 6).

Even before the establishment of a linguistics department at Yale, however, linguistics in some form was taught in nearly every major American university. One of the first projects undertaken by the Linguistic Society of America (LSA), following its founding in 1924, was the 'Survey of Linguistic Studies: Opportunities for Advanced Work in the United States' (Kent and Sturtevant, 1926). All but one of the 26 universities surveyed (those belonging to the Association of American Universities) listed 'courses bearing upon linguistic science' in catalogues and bulletins for the 1926–1927 academic year. Seven institutions had particularly strong offerings, each with 15 or more affiliated faculty members teaching upward of 30 courses: University of California (Berkeley), University of Chicago, Columbia University, Harvard University, University of Michigan, University of Pennsylvania, and Yale University. Twenty-five schools had language (nonliterary) courses in modern and older languages, but the leading programs also offered coursework in general linguistics, general phonetics, comparative Indo-European, and the analysis of American Indian languages.

In 1928, under the direction of Sturtevant, the LSA began holding an annual summer Linguistic Institute, meant to serve both graduate students in linguistics and senior scholars wishing a collegial environment in which to discuss and share research. At the first Institute, 45 people registered for courses, including four members of the faculty. Courses offered at the early Institutes represented the historical interests of the majority of LSA members, with most classes devoted to older languages, their historical development and comparison. In 1928, for example, 31 of the 37 courses were historical. But Sturtevant insisted on also scheduling courses that were not historically oriented – experimental phonetics, methods of analyzing unwritten languages, description of contemporary American English, and fieldwork on the dialects of the United States and Canada. As the Institutes became better known and increasingly prestigious, the offering of such courses spread into university programs. Thirty-five years later, at the 1963 Institute, 37 courses were distributed over four main areas, three synchronic, one diachronic; 220 people registered (1964, *LSA Bulletin 37*: 20). At every Institute, the most well-attended course was 'An Introduction to Linguistic Science.' In 1937 and 1938, the course was especially popular with faculty members as well as students when it was taught by Edward Sapir (1884–1939) and Leonard Bloomfield (1887–1949), respectively.

Bloomfield did more than any other American linguist to shape the teaching of linguistics at American universities in the second quarter of the 20th century. His textbook *Language* (1933) came to dominate the field, and the first two-thirds of it, focused on synchronic analysis, constituted the foundation for American structural linguistics, the paradigm that increasingly displaced more traditional diachronic work as the main orientation of American linguistics. The genius of the text was that it presented historical topics fully and clearly, while at the same time Bloomfield gave priority to a systematic exposition of synchronic descriptive analysis. *Language* was the preeminent textbook in American linguistics well into the 1950s.

In 1941, a "considerable body of linguists assumed the role of active language teachers and attempted wholeheartedly to apply the findings of their science to the practical problems of language teaching" (Moulton, 1961: 82). Many linguists, including Whitney and Bloomfield, had taught languages in college and university and even written grammars and language textbooks for the well-known European languages, but the outbreak of World War II in 1939 directed attention to the need for materials and speakers of languages until then unfamiliar in the American education system. The American Council of Learned Societies in 1941 established the Intensive Language Program (ILP) which employed linguists, mostly recent doctoral recipients with experience in the analysis of American Indian languages, to develop teaching materials based on linguistic analysis. Using these materials, often while they were still in development, linguists established intensive college courses in such languages as Swahili, Hausa, Fanti, Arabic, Chinese, Japanese, and Thai. By the summer of 1942, the ILP was prepared to offer 56 courses in 26 languages at 18 universities. Approximately 700 students enrolled, some of them linguistics majors seeking knowledge of languages distinct from their native English. Over the next two decades, it became common to find linguistics programs requiring their students to gain exposure to such languages.

During World War II, the United States' armed forces adopted the ILP, and linguists were recruited

to prepare language training materials for the military. One result from this concentrated period of pedagogical concern was a close association between linguistics and the less commonly taught languages, not only in research and publication, but also within the administrative structure, and thus the programs, at some universities. A second, related result was the incorporation into linguistics programs of an area commonly referred to as applied linguistics, which concerned the application of linguistic principles to language teaching. Linguistics students now had yet another area of specialization available to them.

Bloomfield's textbook was supplemented in the 1940s by workbooks prepared for phonemics by Kenneth Pike (1912–2000) and for morphology by Eugene Nida (b. 1914). Both contained problems drawn from a wide range of languages and were initially used in training sessions for Christian missionary linguists at the Summer Institute of Linguistics (SIL). From its informal beginning in 1934 with just two students, SIL went on to train hundreds of students each summer in techniques for linguistic field work on undocumented languages (see Robbins, 1977). The texts by Pike and Nida also were adopted at secular colleges and universities for classes on the analysis of linguistic data.

During this period of American descriptivism, from the 1940s until the early 1960s, problem-solving was a key component of the linguistics curriculum, where it prepared students for field research. A good example of descriptivist training was at the University of California, Berkeley, which formalized its linguistics program in the early 1950s, and in 1952 established the Survey of California Indian Languages, directed by Mary R. Haas (1910–1996). The Survey was "funded to allow students to do fieldwork, to write dissertations, and, aided by the University's publication policies, to publish accounts of these Indian languages" (Emeneau, 1997: 618).

The 1950s brought to maturity the American descriptivist approach to linguistics, sometimes referred to as American structuralism. Two widely adopted textbooks appeared, one by Henry A. Gleason, Jr. (b. 1917), the other by Charles F. Hockett (1916–2000). Gleason's *An introduction to descriptive linguistics* (1955) dealt solely with synchronic topics and was accompanied by a workbook of problems. Hockett in *A course in modern linguistics* (1958) followed the pattern of Bloomfield's *Language*, with the first two-thirds of the book devoted to synchronic analysis, the last third to language change, historical reconstruction, and the comparative method. The texts reflected the orientation of mid-century American linguistics with core chapters on articulatory phonetics, American structural phonemics, and morphology. Neither work contained a chapter on semantics, and discussion of syntax was limited. Just a few years later syntax became a major topic in American linguistics with the growing prominence of generative grammar.

Veterans' education benefits led to dramatic increases in undergraduate and then graduate matriculation in the decade following World War II. Linguistics gained students and visibility within the academic world, and a number of institutions formalized their linguistics programs into departments or created new programs. When the United States Congress passed the National Defense Education Act of 1958 (NDEA), the field benefited under provisions that strengthened both science and foreign languages in higher education. Especially important were graduate fellowships under Title IV of the act, which not only provided three years of support to students but also three years of supplementary stipends to the program in which they enrolled. In 1963, five years after the passage of the NDEA, there were in the United States at least 17 departments of linguistics, 14 interdepartmental programs, and 43 other departments offering linguistic coursework; 882 students were enrolled for advanced degrees in linguistics, and 20 institutions offered the baccalaureate degree in linguistics (Newmeyer, 1986: 45–46). Coincidentally, the impetus to graduate study in linguistics provided by the NDEA came just as generative grammar was rising in challenge to the American descriptivist tradition, and the emergence of an exciting new theoretical approach invigorated linguistics as a university subject in America.

Linguistics as a University Subject: Early History, in Europe

T Lindström Tiedemann, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Pinning down the history of the subject of linguistics is complicated by the fact that it is hard to know where to draw the line between linguistics, its subdisciplines and other disciplines. Is the study of specific languages for their own sake and/or in order to understand their literature to count as linguistics? Is there a difference between the teaching and research of classical languages and modern languages? Notably, Morpurgo-Davies has claimed that a German professor of Sanskrit in the 19th century usually had much in common with professors of comparative linguistics (Morpurgo-Davies, 1998: 8). Furthermore, some departments of phonetics later became departments of linguistics (e.g., at Uppsala University, Sweden), so how should we treat them in a history of linguistics as a university subject?

Scholars have been interested in linguistic topics for thousands of years. Still there has been talk about an institutionalization of linguistics during the 19th century (e.g., Morpurgo-Davies, 1998: 3; Hovdhaugen *et al*., 2000: 507). However, in many countries it took much longer for the first chairs in general linguistics to appear. In Scandinavia, for instance, general linguistics has been seen as "closely tied to structuralism" and in some countries even more so to generative grammar (Hovdhaugen *et al*., 2000: 507).

Nevertheless, even before the first chairs in general linguistics appeared, there were chairs established in Comparative Linguistics/Philology, Phonetics, and chairs partly devoted to Linguistics. Moreover, there were already chairs in Latin, Greek, and Oriental languages, usually meaning Hebrew primarily, at most universities during the 17th century. In the 19th century universities started to establish chairs in comparative linguistics, in modern languages, and finally in phonetics and general linguistics.

This must be seen in relation to the more general changes at the universities during the 19th century, the introduction of research alongside teaching and the specialization that replaced academic careers from one professorship to the next all the way up to theology (see e.g., Morpurgo-Davies, 1998: 10).

Germany and the Friedrich-Wilhelm-University in Berlin (today called the Humboldt University), has been recognized as the center for the important changes carried out at universities during the early 19th century. Wilhelm von Humboldt's (1767–1835) idea was that universities had to combine research and teaching. Professors should spend equal amounts of time on both and "teaching should be linked to research" (Hovdhaugen *et al*., 2000: 134). In addition, one should be required to specialize in one field rather than having the possibility of advancing through the various subjects (Hovdhaugen *et al*., 2000: 134–135).

The first university position in linguistics was created for Franz Bopp (1791–1867), who became

Pinning down the history of the subject of linguistics is complicated by the fact that it is hard to know where to draw the line between linguistics, its subdisciplines and other disciplines. Is the study of specific languages for their own sake and/or in order to understand their literature to count as linguistics? Is there a difference between the teaching and research of classical languages and modern languages? Notably, Morpurgo-Davies has claimed that a German professor of Sanskrit in the 19th century usually had much in common with professors of comparative linguistics (Morpurgo-Davies, 1998: 8). Furthermore, some departments of phonetics later became departments of linguistics (e.g., at Uppsala University, Sweden), so how should we treat them in a history of linguistics as a university subject?

Scholars have been interested in linguistic topics for thousands of years. Still there has been talk about an institutionalization of linguistics during the 19th century (e.g., Morpurgo-Davies, 1998: 3; Hovdhaugen *et al*., 2000: 507). However, in many countries it took much longer for the first chairs in general linguistics to appear. In Scandinavia, for instance, general linguistics has been seen as "closely tied to structuralism" and in some countries even more so to generative grammar (Hovdhaugen *et al*., 2000: 507).

Nevertheless, even before the first chairs in general linguistics appeared, there were chairs established in Comparative Linguistics/Philology, Phonetics, and chairs partly devoted to Linguistics. Moreover, there were already chairs in Latin, Greek, and Oriental languages, usually meaning Hebrew primarily, at most universities during the 17th century. In the 19th century universities started to establish chairs in comparative linguistics, in modern languages, and finally in phonetics and general linguistics.

This must be seen in relation to the more general changes at the universities during the 19th century, the introduction of research alongside teaching and the specialization that replaced academic careers from one professorship to the next all the way up to theology (see e.g., Morpurgo-Davies, 1998: 10).

Germany and the Friedrich-Wilhelm-University in Berlin (today called the Humboldt University), has been recognized as the center for the important changes carried out at universities during the early 19th century. Wilhelm von Humboldt's (1767–1835) idea was that universities had to combine research and teaching. Professors should spend equal amounts of time on both and "teaching should be linked to research" (Hovdhaugen *et al*., 2000: 134). In addition, one should be required to specialize in one field rather than having the possibility of advancing through the various subjects (Hovdhaugen *et al*., 2000: 134–135).

The first university position in linguistics was created for Franz Bopp (1791–1867), who became

extraordinary professor of *Orientalische Literatur und allgemeine Sprachkunde* in 1821 and was made ordinary professor in 1825 (Morpurgo-Davies, 1998: 7; Killy & Vierhaus, 1998). Notably, linguistics was only part of his duties. Within 100 years all German universities had one or more positions in linguistics, although this usually meant comparative linguistics (Morpurgo-Davies, 1998: 7, with reference to Wackernagel, 1904: 206).

Before the 19th century, linguistics and language study was a gentlemanly pastime. However, with the expansion of higher education institutions things were changing, making it possible to make a living as an academic specialized in a linguistic subject around the end of the 19th century (Morpurgo-Davies, 1998: 7).

> Nothing was left to the dilettantes and amateurs; science and learning became a profession—a development which in retrospect has perhaps turned out to be not altogether a good thing. (Aarsleff, 1983: 180–181)

> In contrast to the previous centuries, the increased power and prestige of the universities led to a concentration of almost all aspects of linguistic research of any significance in the universities. [. . .] The role played by amateur linguists and other institutions such as academies became more marginal, [. . .] (Hovdhaugen *et al.*, 2000: 135)

Still, it is clear that many of the famous linguists from the 19th century did not hold posts in the subject: Johan Nicolai Madvig (1804–1886) was Danish Secretary of Culture (cf. Hovdhaugen *et al.*, 2000), Rasmus Rask (1787–1832) served as professor of literature, as a librarian, and later finally became professor of Oriental languages (Hovdhaugen *et al.*, 2000: 159), Jacob (1785–1863) and Wilhelm (1786–1859) Grimm worked as ministerial secretaries, librarians, and as professors and librarians at Göttingen after which they taught in Berlin (cf Seuren, 1998: 82), and Humboldt was a minister of the Prussian government. Between 1500 and 1800, linguistic work such as grammars, dictionaries, and historical studies was primarily done by teachers, clergymen, administrators, and not by university professors and lecturers (cf. Hovdhaugen *et al.*, 2000: 26).

During the 17th and 18th centuries, it became common in Scandinavia to hire (although often without pay) people from abroad as language masters, at first primarily to teach French (Hovdhaugen *et al.*, 2000: 27). It was only in the 19th century that universities began to appoint lecturers and professors in modern languages.

It is important to remember that the changes in linguistics during the 19th century were not only due to the interest in the subject itself, but also to the size, importance, and number of the higher education institutions. For instance, Sanderson (1975: 1) has said that British higher education "was never more radically reshaped." At the beginning of the 19th century, England and Wales only had two institutions for higher education: the universities of Oxford and Cambridge (Morpurgo-Davies, 1998: 4) and still before the second world war the only "established posts in linguistics were specialist chairs of Comparative Philology at Oxford, Cambridge and a few other universities and of Phonetics at University College London" (Brown and Law, 2002: vii). That is if we count only comparative philology, linguistics and phonetics, while excluding posts in specific languages.

In addition, it is important to note that at the beginning of the 19th century, the establishment of chairs in the linguistic subjects still did not guarantee the chance to research this subject, since the chairs were still primarily teaching chairs:

> [Friedrich August Rosen] was in 1828 invited to fill the chair of Oriental languages in the London University [. . .] where he taught elementary lessons in Hindustani, Arabic, Persian, and Sanskrit for sixteen hours a week at a guaranteed salary of one hundred pounds a year. (Aarsleff, 1983: 177)

It was not until the end of the war, in 1944, that the first British chair in General Linguistics was set up and J. R. Firth (1890–1960) was elected to it (School of Oriental and African Studies, Department of Phonetics and Linguistics) (Brown and Law, 2002: vii). Oxford and Cambridge were much later establishing departments and chairs in Linguistics, Oxford getting its first chair in Linguistics in 1976 (Roy Harris), Cambridge's first Professor of Linguistics being Peter Matthews who took up this post in 1980 (Matthews, 2002: 207). The University of Edinburgh was, however, earlier in establishing their first chair in Linguistics. There was a department and chair for English Language and General Linguistics between the years 1948–1964. And when the department was split in two (in 1964) a new chair was established for General Linguistics. Interestingly, the new department of General Linguistics did not teach undergraduates in the first years, but instead only had a Postgraduate Diploma and some research students (Asher, 2002: 35; Lyons, 2002: 181).

After the expansion during the 1960s and 1970s, the British universities unfortunately started to experience grant cuts that affected many small linguistics departments, which had to close down or merge with other departments during the 1980s (Lyons, 2002: 189). In recent years, this trend has repeated itself with the decision being taken in 2003 to close down the Durham Department of Linguistics and English

language, followed in May 2004 by the proposed closure of the School of Language, Linguistics and Translation Studies at the University of East Anglia by 2007.

In France all universities were closed as a result of the French revolution and it was not until the 1880s that French universities made a proper come back (Morpurgo-Davies, 1998: 5). Still France had a tradition of studies of oriental languages, including Sanskrit, which as in Germany was in some ways a forerunner of linguistics (Morpurgo-Davies, 1998: 9). Morpurgo-Davies believes (with reference to Auroux, 1983: 253, 1984: 304ff) that linguistics in France really started to establish itself during the late 1860s when Michel Bréal (1832–1915) became professor of comparative grammar, the Société Linguistique de Paris was founded, and the École Pratique des Hautes Études was created (Morpurgo-Davies, 1998: 9).

The situation in Italy was, according to Morpurgo-Davies, very different from that in France, although, like elsewhere, the first chairs in Sanskrit came before the chairs in linguistics (1998: 9). The main difference was that in Italy the new kingdom (1861) made it official policy to encourage "the establishment of new chairs of Sanskrit and of Comparative Linguistics" and so by the 1870s Turin, Florence, Bologna, Pisa, Naples, Rome, and Milan all had chairs in these subjects and Italy was thereby ahead of both France and England (Morpurgo-Davies, 1998: 9–10).

It is important to note that of course a subject is not only taught if there is a professor in it, nor is the creation of a chair or even a lectureship the first sign of interest in the subject. Hovdhaugen *et al.* (2000: 165) mention that even though the Scandinavian universities only hired professors in comparative linguistics from the 1870s, the subject was taught already in the 1840s. Similarly, there have been different ways of making general linguistics part of the education students received. In many parts of Europe, it was introduced through comparative linguistics and Sanskrit. As an example of how it could otherwise be introduced, modern general linguistics started to appear in Sweden during the 1940s when the *Språkvetenskapliga Sällskapet i Uppsala* (the Linguistic Society in Uppsala) arranged a series of

Table 1 Some of the first chairs in linguistics and general linguistics in Europe

Country	*University*	*First professor*	*Subject*	*Year*
Germany	University of Berlin	Franz Bopp (1791–1867)	Oriental Literature & General Linguistics (extraordinary)	1821
Germany	University of Berlin	Franz Bopp (1791–1867)	Oriental Literature & General Linguistics (ordinary)	1825
Germany	University of Halle	August Friedrich Pott (1802–1887)	General Linguistics (ordinary)	1838
Germany	University of Berlin	Heymann Steinthal (1823–1899)	General Linguistics (extraordinary)	1862
France	École d'Anthropologie	Abel Hovelacque (1843–1896)	Linguistic Anthropology	1867
Norway	University of Oslo	Alf Sommerfelt (1892–1965)	General Linguistics	1931

Finland	University of Joensuu	Jussi Niemi (b. 1950)	General Linguistics	1991
Sweden	Uppsala University	Åke Viberg (b. 1945)	Linguistics	2001

introductory lectures on the subject (Hovdhaugen *et al.*, 2000: 333). A few years later it was introduced more formally at Uppsala University through phonetics, in which courses started during the 1950s (Hovdhaugen, 2000: 333). In Gothenburg, there were seminars in the language departments that were organized by the professors of Scandinavian languages, Natanael Beckman (1868–1946) and Hjalmar Lindroth (1878–1947), where one discussed issues in general linguistics at least from the 1930s. In Lund linguistics was primarily introduced from Copenhagen, but there was also a French scholar, Pierre Naert (1916–1971), who taught Saussure to his students of Scandinavian languages between 1939 and 1962 (Hovdhaugen *et al.*, 2000: 334). So by various means, linguistics became a university subject, starting during the 19th century but becoming more firmly established as general linguistics during the 20th century (see Table 1).

Linguistics: Approaches

Introduction

Linguistics is the study of language, and there are many different kinds of linguistics, some mutually compatible, some in competition. This diversity of approaches to linguistics is possible because language does not present itself to investigation as a coherent and well-defined field of enquiry that is clearly distinct from other areas of investigation. Instead, language is best imagined as a landscape through which it is possible to take various journeys, its horizons redefined by each approach.

Most approaches to linguistics agree on a few basic facts about language. The first is the fact of linguistic form. While the status of linguistic form is in dispute (as I show below), it is clear that linguistic events such as utterances or inscriptions must be understood as manifestations of linguistic types. Thus utterances must be understood as tokens of combinations of words, even though it may be impossible to isolate a 'word' in the actual stream of sound. The words belonging to classes (such as 'Noun') are made by selecting sounds from an inventory of sounds (phonemes of the language) and so on; in all cases, language must be understood as drawing on inventories of types and combining those types in regular ways: a word of the type 'Article' precedes a word of the type 'Noun' in English (within the Noun Phrase). These regularities, another idealization away from the crude data, involve rules or generalizations or constraints.

No account of language can ignore the fact that language is ordered and regular, based on an inventory of types and rules of combination that together constitute linguistic form. The second fact accepted by all approaches to linguistics is that form relates to

introductory lectures on the subject (Hovdhaugen *et al.*, 2000: 333). A few years later it was introduced more formally at Uppsala University through phonetics, in which courses started during the 1950s (Hovdhaugen, 2000: 333). In Gothenburg, there were seminars in the language departments that were organized by the professors of Scandinavian languages, Natanael Beckman (1868–1946) and Hjalmar Lindroth (1878–1947), where one discussed issues in general linguistics at least from the 1930s. In Lund linguistics was primarily introduced from Copenhagen, but there was also a French scholar, Pierre Naert (1916–1971), who taught Saussure to his students of Scandinavian languages between 1939 and 1962 (Hovdhaugen *et al.*, 2000: 334). So by various means, linguistics became a university subject, starting during the 19th century but becoming more firmly established as general linguistics during the 20th century (see **Table 1**).

Linguistics: Approaches

N Fabb, University of Strathclyde, Glasgow, UK

Introduction

Linguistics is the study of language, and there are many different kinds of linguistics, some mutually compatible, some in competition. This diversity of approaches to linguistics is possible because language does not present itself to investigation as a coherent and well-defined field of enquiry that is clearly distinct from other areas of investigation. Instead, language is best imagined as a landscape through which it is possible to take various journeys, its horizons redefined by each approach.

Most approaches to linguistics agree on a few basic facts about language. The first is the fact of linguistic form. While the status of linguistic form is in dispute (as I show below), it is clear that linguistic events such as utterances or inscriptions must be understood as manifestations of linguistic types. Thus utterances must be understood as tokens of combinations of words, even though it may be impossible to isolate a 'word' in the actual stream of sound. The words belonging to classes (such as 'Noun') are made by selecting sounds from an inventory of sounds (phonemes of the language) and so on; in all cases, language must be understood as drawing on inventories of types and combining those types in regular ways: a word of the type 'Article' precedes a word of the type 'Noun' in English (within the Noun Phrase). These regularities, another idealization away from the crude data, involve rules or generalizations or constraints.

No account of language can ignore the fact that language is ordered and regular, based on an inventory of types and rules of combination that together constitute linguistic form. The second fact accepted by all approaches to linguistics is that form relates to

meaning. A central function of language is to enable communication, and the organization of linguistic forms has some relation to the organization of meaning. This view – in some form – is shared by many approaches to linguistics: meaning is structured, and the structure of form has some relation to the structure of meaning.

The Status of Linguistic Form

One of the issues that divide approaches to linguistics relates to the 'autonomy' of linguistic form, in a number of senses. One view, expressed from the margins of linguistics or from outside linguistic theory, is that linguists' discoveries of linguistic form are actually determined by their experience of writing (e.g., the notion of the phoneme is a reimagining of the alphabetic letter), and hence that linguistic form is an artifact of a particular moment in the history of work on language. A second view is that form is entirely determined by function; in its crudest form this is the traditional grammar notion that a word is of the class Noun if it is 'a naming word'; more sophisticated accounts might see the class of a word as fully determined by the function of the word relative to other words in the sentence. A third view sees form as autonomous; thus it is a fact about a word that it is a Noun, this having the same determinate relation to the word as its sound structure or core meaning. While it may have other characteristics as a consequence of being in this word class, including function relative to other words or distinctive phonological characteristics (e.g., stress patterns in English), these functions do not determine its status and are in effect implied by its word class rather than presupposed by it.

Of these three views, the first is an antilinguistic approach to linguistics, the second a strongly functionalist approach, and the third, a strongly formalist approach. Within the formalist approach, one of the issues that arise is which forms are primitives and which are compound or derived forms; for example, some approaches treat Noun as a primitive class, while others see it as derived from features, so that a Noun is a composite of two primitive features, +N and -V (while Verb would be -N +V, Adjective would be -N -V., etc.). The most important early discussion of whether forms are primitives is Halle's argument that there is no coherent notion of the phoneme as a primitive of sound structure; it is instead a composite entity built from the phonological features.

Underlying the discussion of the autonomy of linguistic form is the question of whether any kinds of linguistic forms are specific to language or are also found in other domains. A key text is Chomsky's *Syntactic structures* (1957). He begins his book by discussing generic kinds of forms, as expressed by rules that rewrite a symbol as a string of symbols (phrase-structure rules); simple rules of this kind could, in principle, be found in domains (including cognitive domains) outside language. But he shows that this simple kind of rule is inadequate for understanding language and that a new kind of rule – a transformational rule – must also be used. A transformational rule takes a complex linguistic representation (a tree structure) and changes it into another tree structure, and is specific to language; transformational rules crucially do not operate on unstructured strings of symbols (e.g., no rule simply inverts the sequence of a string of symbols) but instead operate on more complex structural representations. Later developments in transformational grammar showed that transformations were subject to various constraints (such as the Complex Noun-Phrase Constraint, which prevented a rule simultaneously accessing something inside and outside a complex Noun Phrase); these constraints again were specific to linguistic form. While it has occasionally been argued that transformational rules are found outside language (e.g., in music), it is likely that this kind of rule, which transforms one complex representation into another, is specific to language. These questions are particularly interesting because the existence of some kinds of forms specific to language would support that language is processed in the mind by modes of cognitive organization specific to language.

A basic idea in linguistics is that linguistic form exists to provide formal choices that have functional (semantic or communicative) consequences. For Saussure, a sign such as the word 'tree' is a pairing of choices from two distinct systems: (1) the sound system, where the choices produce the three-sound sequence that make up the spoken word and (2) the meaning system, where the meaning of 'tree' is chosen from a range of possible meanings. The pairing of sound and meaning is thus a matter of choosing from different inventories. Choice is a dominating principle in Saussurean linguistics and, later, in structuralism, including the nonlinguistic structuralism found in the work of Roland Barthes such as *The fashion system*.

Systemic functional grammar is one of the major approaches to linguistics in which the notion of choice has been fundamental. Each 'system' in systemic functional grammar presents ranges of options to choose from when communicating, and the theory investigates the functions expressed by making these choices. This approach has enabled systemic functional grammar to pioneer work in certain areas of linguistic description, some of which (such as

Halliday's early work on thematic roles) have been absorbed into other linguistic theories. In particular, systemicists are interested in the choices among 'cohesive devices' in discourse, the devices – conceived of as choices from a range of options presented by the system – explicitly guiding the hearer or reader in understanding how sentences are related.

Systemicists have developed an account of 'register,' the set of linguistic features associated with specific genres of verbal behavior (formal interview, informal letter, etc.), where the term 'register' itself is another way of saying 'range of options from which to choose.' In addition, systemic functional grammar has a deep interest in stylistic analysis, in which formal choices have functional significance in expressing complexities and nuances of meaning and fit well with 'close-reading' approaches in mainstream literary criticism.

Another fundamental idea, shared to some extent by all approaches, is that linguistic form is the mediation between a thought and an utterance; that is, that linguistic form enables the expression of meaning in sound (and writing). Chomsky's 'minimalist enquiries' begin by re-examining this basic idea. From his earliest work onward, Chomsky's approach to linguistics has always been to ask what the simplest kind of language might be, and then to ask why actual human languages are not this simple.

Thus, as described above, *Syntactic structures* establishes that sentences of a natural language cannot be generated just by rules (phrase-structure rules) of a certain low level of complexity, but require a more complex kind of rule, one that in turn requires a whole theory of linguistic representations which can be subject to transformation.

'Why aren't sound and meaning fully aligned?' is a recently formulated minimalist question; the answer is that organizations of the sentence as meaning are not isomorphic with large-scale organizations of the sentence as sound. In Chomsky's always-provocative terminology, the question is why language is 'imperfect.' Consider, for example, the Noun Phrase that expresses the thing eaten in 'John ate the cheese'; here this unit of meaning is after the verb, but it is before the verb in 'the cheese was eaten' and the word 'what' (which substitutes for it, i.e., 'the cheese') is at the beginning of the sentence in 'what did John eat?' Perhaps the unit of meaning does not always stay in the same place because some other principle, possibly involving the informational structuring of the utterance, forces it to move. Chomsky sees this as an 'imperfection,' and seeks to explain why moving the unit is a necessary compromise among the various demands placed on linguistic form by the requirement that speech expresses meaning.

Rationalist and Empiricist Approaches and the Status of Data

A major division in approaches to linguistics pits rationalists against empiricists, as their attitudes towards data exemplify. The key figure for rationalist approaches is Noam Chomsky. Most kinds of linguistics before Chomsky were empiricist approaches (as in the work of Bloomfield), and Chomsky defined his linguistics in opposition to those. Data always present a problem for linguistics, because it must always be idealized; two slightly different utterances of the same word must be understood by linguistic theory as two tokens of the same type. Without this idealization, there would be nothing to say about language.

Approaches differ in the kinds of idealizations they adopt. Chomsky famously and substantially idealized so that the rules in *Syntactic structures* generate an (infinite) set of sentences corresponding to the set of sentences accepted as grammatical by an idealized user of the language, having separated out all contextual and behavioral factors. The rules describe what someone knows to be grammatical (his or her 'competence'), not what that person actually says.

Since this rationalist approach to linguistics aims to describe a person's knowledge of language, not his or her linguistic behavior, there are some significant consequences for the status of data. First, data must be sifted into the relevant and the irrelevant (for this particular purpose); data irrelevant for theoretical syntax might of course be relevant in a different kind of linguistics. It is never clear in advance whether data will be relevant or irrelevant. For example, in *Syntactic structures* Chomsky demonstrates that transformational rules can explain the various configurations of modal, auxiliary, and main verbs in an English sentence; on the other hand, it's also possible, since a finite and small number of such possible configurations exist, that they could actually just be learned as fixed sequences with no rule involved. There is no guarantee in advance that either approach will be correct.

The second major consequence of a rationalist approach to data is that the frequency of any particular kind of data is ignored, both in the sense that in Chomskyan linguistics 'variability of rules' is generally ignored (see discussion below) and in the sense that statistically very rare data may nevertheless have a key theoretical role. Thus, in the early 1980s the rare 'parasitic gap constructions' were first discussed; an example is the grammatical sentence 'Which books did you put on the shelves without reading?' where the phrase 'which books' matches not one but

two gaps in the sentence (after 'put' and after 'reading'), one of which is called parasitic. Sentences like this are unlikely to turn up in a corpus, and there are no descriptions of them before this time; nevertheless, such sentences played a major role in helping us understand fundamental aspects of the workings of sentence structure.

The third major consequence for data under a rationalist approach is that these data are invented in order to test the predictions of the theory (i.e., invented and then tested against speakers' judgments), rather than gathered and used in constructing a theory. Rationalist approaches to linguistics must assume that the theory will guide the interpretation of the data.

In contrast, empiricist approaches treat theories as constructs that emerge from data. These data may be gathered into a corpus. A fundamental concern is to develop a methodology for gathering, annotating, and understanding the data. Note that rationalist approaches to linguistics do not have this commitment to a methodology, and one of Chomsky's aims in *Syntactic structures* was to wrest American linguistics from the heavily method-oriented approach associated with the structural linguistics of the 1930s and 1940s.

One advantage of the empiricist approach is its inherent ability, more so than a rationalist approach, to guarantee a result in the sense of a description or annotation of linguistic data. An empiricist approach can be conceptualized as a plan of action, with steps to be followed using clearly specified methods in order to process a collection of data into an account. Because an empiricist approach is supported by agreed methodologies, it can be used to gather and organize large amounts of data, and it is sometimes favored in language work when large amounts of information must be gathered before that information (e.g., from 'endangered languages') becomes unavailable.

This kind of empiricist approach also favors the social over the cognitive, because what is gathered is what people say or write, rather than what they know. It has been argued (for example, by Ken Hale) that a rationalist approach, despite its associated risks, is nevertheless best even for endangered languages, because we should be interested in these speakers' knowledge of their language, not just in their utterances.

While approaches to linguistics agree on the existence of linguistic form, they disagree on how inclusive such a theory of linguistic form should be. One area of disagreement is language statistics. As with any collection of data, linguistic data can be subjected to statistical analysis and this statistical analysis can be described in terms of linguistic rules.

It is a fact that some linguistic rules are 'variable' for an individual speaker or for a speech community (the term 'variable rule' comes from Labov); an example would be 't-glottaling' in British English or the 'r-drop' in some varieties of American English. T-glottaling is the use of a phonetic glottal stop where there is a phonemic /t/ in a word like *bottle* and that can be understood as a consequence of applying a rule changing /t/ to the glottal. Data gathered for a particular individual will show that the rule is used at some times and not at others, and that these data could be described by attaching a percentage to that rule for that individual (for that data) to indicate how frequently the rule is actually applied in a particular context. The percentage might differ with the social context; for most speakers, t-glottaling is more likely in more informal contexts, and this information could be appended as a statistic to the rule.

The issue dividing approaches to linguistics is whether a way of relating that percentage to the rule can be built into the theory and the representations it permits. The decision depends in part on whether the theory aspires to the holistic or the modular. Holistic theories attempt to incorporate as much explanation of language as possible within a single, connected theoretical model, e.g., Systemic Functional Grammar. Such theories tend to be functionalist and tend not to allow for significant autonomy of form; the holism here claims an explanatory link among various different aspects of language.

Modular theories, on the other hand, are theories that divide language into different subfields – each with its own theoretical account – where there may be limited or no relation among the theories. Modular theories, of which generative grammars are a good example, place considerable emphasis on the autonomy of linguistic form. While generative linguistics on the whole is not interested in statistical facts, Optimality Theory (which has emerged from generative linguistics) is interested; it has had a consistent interest in statistical facts, and various ways have been suggested of incorporating statistical facts into the ranking of constraints.

The distinction between rationalist and empiricist approaches is sometimes entangled in a rhetoric of 'realism' or 'naturalism.' The terms 'natural' or 'real/realistic' may be used to valorize certain kinds of (usually empiricist) linguistic theory; hence there is talk of 'natural phonology,' 'psychological realism,' or 'real language.' The underlying assumption in each case is that how linguistics proceeds should be subject to some external constraint on theory-formation, but that is in conflict with the basic principle of rationalist approaches that no theory is guaranteed by some external constraint to be right or successful.

Most commonly, external constraints are drawn from computer science or from psychology, but sometimes a demand is heard that linguistic theory should be constrained by a particular audience's need to understand it. In each case, these demands are driven by practical anxieties, usually fundamentally financial: Can the theory be used to develop working software? Can it serve psychology? Will the general public understand it sufficiently to want to support it? Will the linguistics department survive the next round of university cost-cutting?

The Production of Form

All approaches to linguistics agree there is linguistic form. As I have suggested above, these approaches differ on which forms are considered fundamental; for example, are phonemes a fundamental kind of form, or are they a construct based on phonetic features that themselves are the fundamental kinds of forms? They also differ in how linguistic form is generated. What kinds of rules build form? What are the constraints on the operation or output of those rules? Much of the debate in this area has been conducted within kinds of linguistics that refer to themselves as 'generative' and trace their intellectual ancestry back to *Syntactic structures*, a book that is a key discussion of the role of rules in language.

In early generative linguistics, there were just rules. These were phrase-structure rules that built a representation called a tree structure, which terminated in a string of words that made up a grammatical sentence, and there were transformational rules that changed one tree structure into another. Within a few years, it was noted that transformational rules were subject to constraints, and these were explored fully by J. R. Ross, who in 1967 wrote one of the most influential Ph.D. dissertations in linguistics, 'Constraints on Variables in Syntax' (published as *Infinite Syntax!*, 1986). Ross (1967) showed that the possibility of changing one tree structure into another was prevented if the transformational rule needed to relate two positions, one of which was in an 'island' (a relationally defined subarea within a tree structure, such as a sentence inside a noun phrase). This meant that in addition to rules that generated form, there were also constraints on the rules.

The balance between rules and constraints – both in terms of number of rules as opposed to constraints, and complexity of rules as opposed to complexity of constraints – has changed over the course of generative linguistics and is different in different approaches. For example, by the early 1980s, transformational rules were as simple as the rule 'move something' (technically formulated as 'move alpha'), while the constraints on this simple rule were quite extensive and complex.

In addition to constraints on rules, another kind of constraint was introduced: a constraint (or 'filter') on the output of the rules. The best known filter in generative syntax of the 1970s was the 'that-trace' filter; this stated that a transformational or other rule could not have as its output a sentence in which the subordinating conjunction **that** was followed by a 'trace' (an empty subject). Thus the sentence 'Who did you say that left?' is ungrammatical because **that** is followed by an empty subject.

Given the possibility of having rules, constraints on rules, and constraints on outputs, some theories have attempted to dispense with one of these elements. In the syntactic theory of the early 1980s called 'government-binding theory,' the terms government and binding did not describe rules but were best understood as expressing constraints on relationships among parts of the tree structure; the role of rules was minimized. In Optimality Theory, both in syntax and in phonology, the role of form-generating rules is minimized, and there are no form-changing rules (such as transformational rules); instead, the burden of explanation is carried by constraints on output.

Optimality Theory, which has been dominant in approaches to sound structure, participates in a key debate about order. In Optimality Theory, constraints are ordered (the term 'ranked' is used) in the sense that an output may violate a constraint and yet be preferred to an output that violates another constraint, because one constraint is ordered above the other. However, this order is fundamentally different from that of the generative phonology that dominated phonology before Optimality Theory, and Optimality Theory now challenges it. In this generative phonology, rules are themselves ordered, such that the input of one rule is determined by the output of the preceding rule. Rule ordering is also the basis of the phonological cycle, where a sequence of rules is applied to a word, then morphological rules are applied (e.g., it is suffixed), and then the same sequence of phonological rules is applied again from the beginning.

The 'Landscape' of Language and its Division into Fields of Linguistic Inquiry

As we have seen, approaches to linguistics can disagree on what aspects of language are open to theoretical description. Alternatively, these approaches may agree on what should be described but dispute the subfield most suited to describing it. Linguistic theory is conventionally divided into distinct but related subfields. For sound structure there is a distinction between

phonetics (itself potentially distinguished into acoustic and articulatory phonetics) and phonology; phonetics deals with the mediated manifestations of sound, while phonology deals with the knowledge of (representations of) sound. Here a 'border dispute' involves the distinctness of phonetics and phonology and whether the same kinds of description – e.g., the same kinds of articulatory feature – can be used explanatorily in both phonetics and phonology.

The distinct status of morphology is another area for dispute. In some theoretical frameworks, morphology and phonology are closely intertwined (e.g., lexical phonology and morphology), and thus questions arise about the similarity between morphological and phonological processes. Some morphological processes, such as reduplication (where part of a word is copied to build a larger word), raise difficult problems for phonology. However, morphology is also syntactically relevant, and it is possible that the internal structure of words – the domain of traditional morphology – can in some cases be opened up to syntactic rules. Reorganizing subkinds of linguistics relative to one another can create very productive ways for approaches to linguistics to develop and change.

Another border under dispute is that between the syntax and the pragmatics. This can involve matters of information structure, as well as problematic areas of the syntax such as apposition and conjunction, where there may be pragmatic explanations for apparently syntactic processes. Does the organization of discourse require its own subfield ('discourse analysis') or can it be entirely incorporated under the field of pragmatics? Could a theory of discourse analysis better explain coreference than the syntax?

In his recent work, Chomsky argues that some phenomena previously understood as syntactic are better understood as phonetic – explained as part of the 'phonetic form' of the sentence rather than its syntactic form. Here, for example, an interesting issue is whether the linear order of syntactic elements (such as words) can be entirely explained by some nonsyntactic principle such as the phonetics, on the basis that syntax is the study of hierarchy and phonetics the study of sequence.

Approaches to linguistics can thus differ according to the linguistic material that experts think they can explain under their own subfield. But it is also possible for approaches to different kinds of data to share similar ways of theorizing, a fact that has interesting implications for the organizations of different kinds of linguistic cognition corresponding with these theories. The most significant interplay among domains is seen in generative phonology and generative syntax. At times these have been very close – and at other times very different – in their approaches, raising the question as to whether there are good reasons for thinking that phonology and syntax are fundamentally alike or fundamentally different.

A historical connection, now broken, was in the idea of the 'cycle,' where a linguistic object (such as a word including several suffixes or a sentence including several subordinate clauses) was built in stages; at each stage, the full set of rules was run through in sequence, starting again from the beginning at the next stage. For a period, it seemed that both words and sentences could be understood as constructed 'cyclically' in this way. While the basic notions of this cycle still survive in some forms and in some types of linguistics, few would now argue for the cycle as a point of similarity between the two theories.

Another rich collection of interconnections involves the notion of the 'feature,' an idea that also jumped from linguistics to Claude Lévi-Strauss's anthropology in the 1940s. Form understood as a set of features – each valued as + or − (such that two features can build four derived forms) – has not only been central to generative phonology, but also borrowed as an idea for (1) syntactic categories (e.g., the category of noun is a derived form based on the features +N −V), (2) semantic categories (e.g., 'agent'), and (3) in lexical semantics (where meanings are considered composites of underlying 'meaning features').

More recently, the principles of Optimality Theory, which have been widely used in phonology, have been borrowed to explain syntactic phenomena. Thus, one characteristic of approaches to linguistics is a willingness to borrow ideas from other domains. When the same idea works in different linguistic domains, this promises to tell us something fundamental about the organization of linguistic form.

Literacy Practices in Sociocultural Perspective

J Collins, University at Albany, SUNY, Albany, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

This article discusses some of the things meant or intended when researchers refer to 'literacy practices.' One meaning is that the researchers will treat literacy as an event in which the (arti)facts of inscription cannot be separated from persons, settings, and other communicative modalities. In addition to this descriptive aim, the term also usually signifies a theoretical ambition. Across multiple disciplines of social inquiry, reflecting the legacy of thinkers such as Sahlins, Williams, Foucault, Giddens, and Bourdieu, the term 'practice' has come to signify a range of theories and frameworks that grapple with the interplay of structure and construction, history and agency (Ortner, 1984). Although a literacy event may be as personal and fleeting as jotting down a list or glancing at an advertisement, literacy understood as the making or interpreting of inscriptions has a history of many millennia, and is closely associated with long-term and large-scale enterprises, such as cities and states, armies and schools, extensive markets and world religions. Relating the personal to the large-scale, the fleeting to the enduring, subject to structure, is thus a challenge confronting the study of literacy practices.

The term 'New Literacy Studies' (NLS) denotes a broad framework, drawing together various critical approaches within the field of literacy studies, consciously built upon the notion of literacy as a **practice**, rather than, say, a psychological skill or abstract social property. Within the NLS framework, literacy practices have been explicitly discussed as entailing a twofold research intention: (a) to build upon the notion of literacy as a communicative event, itself derived from the anthropological ethnographies of communication paradigm, but also (b) to push analysis beyond events to the ideological framing and institutional contextualizing that gives particular events their broader significance (Street, 1993). In this effort, NLS work has drawn particular inspiration from the ground-breaking research of Shirley Heath on literacy events, and it has used the anthropological notion of 'cultural model' to explore relations between consciousness and institutions. It has also, however, been informed by European and English traditions of critical discourse analysis, which call for the study of language as a social practice, an approach to language/society informed by Marxian analyses of ideology and hegemony and Foucault's arguments about discourse, knowledge, and power (Rogers, 2003).

In what follows, I first discuss work in the latter 'New Literacies' (NLS) framework, then indicate amplifications and framings suggested by sociocultural perspectives drawn from anthropology and linguistic anthropology (LA), arguing that the differing approaches only partly overlap. The article concludes by addressing contemporary literacy problems in the US and the complementary strengths and weaknesses of the two approaches (NLS and LA) in thinking about those problems as well as in providing frameworks for more general understandings of the phenomena of literacy and practice. It goes without saying, an article of this scope will unavoidably be schematic, citing only directly relevant work, leaving much that is worthwhile unmentioned and treating as settled much that deserves further argument.

Literacy Practices in the New Literacy Studies

As noted above, within the NLS approach, priority is given to studying literacy events, the situated doings that involve acts of reading, writing, or both. Highly influential early work was that of Heath (1983), who showed that in home, school, workplace, or church, what was a issue was not a binary contrast between literacy and orality, but rather the socially situated and culturally mediated events – whether reading a bedtime story or reading the mail, filling in a job application or composing a prayer for a church service. Participating in such events, people not only decoded or encoded text but were socialized into and enacted particular views of what reading or writing might be, who took what roles in such events,

with one's viewpoint. He claimed that philosophy is the theory of science, the subject of which is the study of human cognition. Thus, he supplemented his researches with psychological evidence and data now referred to as semantic. Twardowski divided the cognitive psychical phenomena into **representations** and **statements**; the former into **images** and **conceptions**. According to this distinction, representation is not an element of a statement, but a necessary condition of it (idiogenetic theory of statements). For example, the conception of a rectangle consists of an image of some plain geometric figure that the agent complements with another two characteristics: rectangular and equilateral.

Apart from investigating purely scientific problems, Twardowski cultivated a rule of clear speaking according to his saying, 'the one who speaks unclearly, thinks unclearly,' in which he always called for proofs of every statement and avoided speculations. Later, his students formed the Warsaw-Lvov School of Philosophy, and, since they followed Twardowski's ideas, it was a school of analytic philosophy. Twardowski died on February 12, 1938 in Lvov.

20th-Century Linguistics: Overview of Trends

G Graffi, University of Verona, Verona, Italy

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Two theoretical trends can be considered as hallmarks of 20th-century linguistics: structural linguistics and generative grammar. They almost equally divide this epoch: structural linguistics (or, shortly, structuralism) flourished between the 1910s and the 1950s, generative grammar from the 1950s. Structuralism was not a unitary theory, but rather a galaxy of schools sharing some principles; furthermore, some important differences distinguish European structuralist schools from the American one. Generative grammar, instead, originated as a unitary theory, which subsequently divided into different schools and which stimulated several alternatives from scholars not accepting it.

Both structural linguistics and generative grammar also had an impact outside linguistics: between the 1950s and 1970s (especially in France), the former became the model for all humanities, hence a 'structural' anthropology, a 'structural' sociology, etc., were developed. Generative grammar, in its turn, was seen as one of the initial steps of the so-called cognitive revolution. Neither of these extensions was free of problems: in many cases, concepts of structural linguistics were applied to other fields with some illegitimate modifications, and the debate on what 'cognitive' really means has not yet come to a solution. All this, however, does not lessen the outstanding role of both structuralism and generative grammar within 20th-century linguistics and within 20th-century thought in general. This article will therefore focus almost exclusively on these two theoretical trends: even sociolinguistics will be dealt with rather as an alternative to generative grammar rather

than in its applied aspects (language policy, etc.). Also other fields, such as language teaching, experimental phonetics, and so on, will not be presented in this overview: this does not mean that they have not reached important results during the 20th century.

20th-Century Linguistics vs. 19th-Century Linguistics: Continuities and Breakthroughs

It is a widely held opinion that the 19th century has been 'the century of comparative and historical linguistics' and the 20th century that of 'general' or 'theoretical' linguistics. Such an opinion is certainly not ungrounded, but it needs some qualifications. Indeed, historical linguistics in the modern sense originated in the 19th century and experienced an astonishingly fast development: in the course of about 80 years, the whole structure of historical-comparative grammar of Indo–European languages reached its final form. Later discoveries (e.g., of languages like Hittite or Mycenaean Greek) added some new data, but the overall architecture built by the Neogrammarians nevertheless remained valid, and it is still today the frame of reference for any historical linguist working in the domain of comparative grammar of Indo–European languages. However, historical-comparative grammar was not the only subject investigated by 19th-century linguists; as a matter of fact, many of them dealt with topics that one would certainly label, today, 'general linguistics.' This phrase may refer to somewhat different research perspectives, as, e.g., (1) speculation on language in general, hence also on language change (and investigation of the principles of historical linguistics plainly enters into this kind of research), and (2) all kind of linguistics that is not historical ('synchronic,' or 'panchronic' in Saussure's terms). Both kinds of general linguistics were practiced during the 19th century. W. von Humboldt (1767–1835) was not an isolated exception: his speculations on the nature of language and his typological classification of languages were developed by several of his followers, such as Heymann Steinthal (1823–1899), Georg von der Gabelentz (1840–1893), and Franz Misteli (1841–1903). But also the first generations of comparative linguists had the study of language in general as their first goal. For example, Franz Bopp (1791–1867) reconstructed Proto-Indoeuropean verbal forms according to a scheme of verb phrase, which is heavily influenced from Port-Royal views. Even August Schleicher's (1821–1868) views about language and language change belong to 'general linguistics' in the former of the senses alluded to earlier. The debate of the 1880s, about the 'sound laws' (*Lautgesetze*), possibly marks the highest point of this kind of general linguistics: shortly after conclusion of such debate, it gradually became less and less important. A 'paradigm' in the Kuhnian sense has developed: the majority of scholars consider only a given set of problems as 'scientific,' namely those of a historical kind. This paradigm is general labeled as the 'Neogrammarian' one: but it cannot be forgotten that many of the Neogrammarians also dealt with topics of general linguistics in both senses quoted earlier. The often labeled 'Neogrammarian Bible,' namely Hermann Paul's (1846–1921) *Prinzipien der Sprachgeschichte* (I ed. 1880; V and last ed. 1920), deals with topics both of historical linguistics and of general linguistics. For example, Paul defined some oppositions that seem to foreshadow some Saussurean dichotomies (see next section) – that of 'descriptive grammar' vs. 'historical grammar' (which could be held to correspond to that between synchronic and diachronic linguistics), or that of 'individual linguistic activity' vs. 'linguistic usage,' which could be considered analogous to that of *parole* vs. *langue*. Similar distinctions were also introduced by Gabelentz in his *Sprachwissenschaft* (I ed. 1891; II ed. 1901), where three meanings of the term *language* (*Sprache*) are distinguished: (a) 'discourse' (*Rede*); (b) 'a totality of expressive means for any thought'; and (c) 'linguistic capacity' (*Sprachvermögen*), i.e., "a faculty innate to all peoples of expressing thought by means of language." Sense (a) could be made to correspond to Saussure's *parole*, sense (b) to *langue*, and sense (c) to *faculté de langage*. Even if it is quite probable that Saussure knew both Paul's and Gabelentz's work, such correspondences are more seeming than real, as will be seen in the next section. The fact cannot be overlooked, however, that such matters typically belong to general linguistics. As can be seen from their life dates, neither Gabelentz nor Paul were much older than Ferdinand de Saussure (1857–1913): why, then, are they normally presented in histories of 19th-century linguistics, whereas Saussure is considered as the 'father' of 20th-century linguistics? This is mainly due to the fact that Saussure and his followers dealt with more or less the same stuff, but in a different perspective. Summarizing so far, one could say that topics in general linguistics show a continuity between the 19th and 20th centuries, but the way of looking at them shows a definite breakthrough.

Ferdinand de Saussure

As is well known, Saussure's *Cours de linguistique générale* (Saussure, 1922) was not directly written by him, but it was compiled by two former students,

Charles Bally (1865–1947) and Albert Sechehaye (1870–1946), on the basis of the notes from class lectures given by Saussure in the academic years 1906–7, 1908–9, and 1910–11 at the University of Geneva. It is perhaps lesser known that neither Bally nor Sechehaye attended any of these lectures: they simply reworked and systematized the notes that others had passed to them. As a result, their reconstruction is often considered not quite faithful to the authentic Saussurean thought, especially after detailed studies of the handwritten notes by Godel (1957) and their edition by Engler (1967–74). Tullio De Mauro's very detailed and insightful commentary on the *Cours* (published since 1972 together with Saussure's original text) stresses many points of Saussure's original thinking that were more or less modified by the editors. Today the exact knowledge of Saussure's ideas cannot be gained without the support of De Mauro's commentary and/or the attentive reading of Engler's edition. Nevertheless, because only the Bally–Sechehaye edition was available until the 1960s, this text actually influenced the immediately subsequent linguists. Hence, reference will be made in what follows almost exclusively to the Bally–Sechehaye edition.

Saussure's linguistic views are standardly epitomized by his so-called dichotomies: (1) *langue* vs. *parole*; (2) synchrony vs. diachrony; (3) signifier vs. signified (*signifiant* ~ *signifié*); and (4) associative vs. syntagmatic relations. (1) opposes the social aspect of language, the code shared by a speaking community (*langue*), to the individual speech act (*parole*); (2) opposes the state of a language at a given moment of its history to its change during the time; (3) defines the 'two sides of the linguistic sign,' namely the 'acoustic image' and the 'concept'; and (4) opposes the relation between elements in succession, such as *teach* + *ing* in *teaching*, to that between elements alternative to each other: e.g., *teaching* as alternative to *learning*, or *studying*, etc. All these dichotomies were surely attested in 19th-century linguistics: that of the social vs. the individual aspect of language was already sketched among others by Paul and Gabelentz (see previous section; it must be added that Saussure also hinted at the notion of *faculté de langage*, language faculty, which shows analogies with Gabelentz's *Sprachvermögen*); the synchrony/diachrony opposition could have a foreshadowing in Paul's distinction between 'descriptive grammar' and 'historical grammar'; the idea that the linguistic sign is two sided, in the sense that the meaning is not external, but internal to it, could be traced back even to the Stoics; and also the existence of two kind of relations in language could already be found, e.g., in some of Paul's pages. Two features, however, strongly differentiate Saussure from his predecessors: (1) a systemic approach, and (2) a strong tendency to define the basic concepts of linguistics without anchoring them to other disciplines, such as sociology, psychology, etc. Saussure's key notion is that of language (*langue*) as a 'system of signs,' each of which has no intrinsic value, but whose value is determined solely by their relationships with the other members of the system ("*dans la langue, il n'y a que des différences*"; Saussure, 1922: 166; original emphasis). This sign system is the code shared by all members of a linguistic community, and its only root lies in this common sharing, because linguistic signs do not have any intrinsic value. Linguistics is a part of a more general science called semiology, namely "*une science qui étudie la vie des signes au sein de la vie sociale*" (Saussure, 1922: 33; original emphasis). *Langue* is therefore a social notion because of its character of semiological code: *parole* is the use by the individual of this general code. Because linguistic signs have no foundation in external reality, but are purely differential entities, they can change across the time; this is the reason for the distinction between synchrony and diachrony. In Saussure's view, however, system exists only in synchrony, at a given moment of time; diachrony does not concern systems, but only isolated elements. A linguistic change is therefore isolated and fortuitous; only when a given sign is changed, a new system is formed, because the relations between signs are different from earlier. Finally, associative and syntagmatic relations are synchronic, because they are essentially systematic.

Saussure's view of language paved the way to what was later called structural linguistics. Even if neither 'structure' nor 'structural' (but just *système*) occur throughout Saussure's text in a technical sense, the systemic approach to language and the definition of linguistic notions and categories on a purely linguistic basis (i.e., without reference to psychological categories, and so on) became the starting points of structural linguistics.

Saussurean Trends in Europe

Geneva School

The editors of Saussure's *Cours*, namely Bally and Sechehaye, were only weakly influenced by the systemic and autonomous approach to language developed in that book. This may seem paradoxical, but it has to be kept in mind that both Bally and Sechehaye had completed their linguistic formation before Saussure's lectures in general linguistics. Among Saussurean notions, Bally especially deepened the *langue/parole* opposition. According to him, *langue* preexists *parole* from a *static* point of view. This relationship, however, is reversed from the

genetic point of view, because *parole* preceded *langue* in the genesis of language (see, e.g., Bally, 1965). Sechehaye was concerned with problems of general linguistics and its relationships with psychology and sociology since his first book (Sechehaye, 1908); in subsequent years he analyzed some fundamental problems of syntax, such as the notion of sentence. These analyses are insightful, but essentially extraneous to the structuralist trend. A stronger structuralist approach characterizes the work of Bally's pupil, Henri Frei (1899–1980); he revisited Saussure's ideas on syntagmatic and paradigmatic relationships, on the one hand, while on the other hand he confronted other descriptions of syntactic structure, mainly those of Bloomfield and of the American structuralist school (see later discussion).

Prague School

The so-called Prague School was formed by a group of linguists belonging to the 'Prague linguistic circle,' founded in 1926 by the Czech anglicist Vilém Mathesius (1882–1945). Members of this circle were, among others, the Russian scholars Serge Karcevskij (1884–1955), Roman Jakobson (1896–1982), and Nikolaj S. Trubeckoj (1890–1938). Prague School dealt with a variety of topics, from English syntax to literary criticism; however, it is especially known for its critical development of Saussurean notions expounded in the theses presented to the first International Congress of Linguists ('Prague Theses,' 1928) and for the contributions of some of its members to phonology (especially Trubeckoj and Jakobson). Among the most influential statements contained in Prague Theses, the following two can be quoted: (1) language is a functional system, whose goal is communication; and (2) the synchrony/diachrony dichotomy is not so neat as Saussure presented it: on the one hand, no linguistic state can be considered as totally independent from evolution and change; on the other, phonetic change is not blind and unsystematic as Saussure assumed, but it must be considered in the framework of the sound system that underpins it.

The most important Prague work on phonology is surely Trubeckoj's posthumous and unfinished *Principles of phonology* (Trubeckoj, 1939). Phonology was defined by Trubeckoj as "the science of sounds of *langue*," whereas phonetics is "the science of sounds of *parole*." The key notion of phonology is phoneme. Phoneme (the phonological unit) is opposed to sound (the phonetic one): the former is abstract, the latter is concrete and 'realizes' the phoneme. When two sounds occur in exactly the same positions and cannot be changed without a change in the meaning of the words, they are different realizations of the same phoneme ('rule 2' of Trubeckoj, 1939): e.g., English [t], [p], and [k] realize three different phonemes, /t/, /p/, and /k/ because they distinguish, among others, the three words *tin*, *pin,* and *kin*. Two sounds may be different and nevertheless belong to the same phoneme: for example, English [t], [p], and [k] in the preceding examples are produced with an extra puff of air, but this puff of air does not occur, e.g., in *spin*. These two sounds do not distinguish any meaning: they are variants of the same phoneme. Phoneme inventories differ from language to language: sounds that realize the same phoneme in a language may be realizations of different phonemes in other languages. For example, aspirated stops are variants of the same phoneme in English, but they realize a phoneme of its own in Hindi.

Since the late 1940s, Jakobson remarked that phonemes are not the 'smallest distinctive units,' but they are actually constituted by even smaller entities, the distinctive features. For example, /d/ differs from /n/ (cf. *dine* vs. *nine*) because of the feature 'nasality'; and it differs from /t/ (cf. *do* vs. *to*) because of the feature 'tensedness.' During the 1950s, Jakobson, together with Morris Halle (b. 1923) further worked out his theory: any phoneme of any language is analyzed as containing or not containing a given feature from a universally fixed set of 12 (later 14) features, whose values are + or −; (binary value, hence the label of binarism given to the theory). For example, English /t/ would have the following features: [-vocalic], [+consonantal], [-compact], [-grave], [-nasal], [+tense], [-continuous] (for the meaning of these terms, see Jakobson and Halle, 1956). Both consonants and vowels are defined on the basis of the same features, and all languages have only this inventory of features at their disposal (but some languages exploit only some of them). Jakobson's binarism was adopted (with some modifications) also by generative phonology (see discussion under Generative Phonology Section).

Copenhagen School

The most well-known linguists of the 'Copenhagen school' are Viggo Brøndal (1887–1942) and Louis Hjelmslev (1899–1965). Both scholars vigorously maintained the structuralist point of view and their Saussurean heritage. Nevertheless, their approach to language in general and to syntax in particular shows many differences; whereas Brøndal considered *language* to be based on logic, Hjelmslev's program was to give *linguistics* a logical basis, in the sense of the 'logic of science,' which was being developed in the 1930s by the neopositivistic philosophers.

In his most important book, Hjelmslev (1943) aimed at constructing a deductive theory of language that he dubbed glossematics. Such a theory should be based on purely linguistic notions ('immanent linguistics') and should follow rigorous methodological standards (it has to be "self-consistent, exhaustive and as simple as possible"). Hjelmslev assigned special importance to Saussure's statement that "language (*langue*) is form, not substance." He therefore distinguished form and substance both on the phonological and on the syntactico-semantic level (expression plane and content plane respectively, in his terms). On the expression plane, a continuous stretch of sound can be differently articulated, according to the different phonemic inventories: e.g., where English distinguishes three nasal phonemes (/m/, /n/ and /ŋ/), Italian only distinguishes two (/m/ and /n/). On the content plane, the same continuum can be differently subdivided: e.g., English divides the color spectrum from green to brown in four sections (*green*, *blue*, *gray*, *brown*), whereas Welsh divides it in three (*gwyrdd*, *glas*, *llwyd*). Both planes are analyzable, according to Hjelmslev, into smallest units, which are limited in number, that he called figuræ: expression figuræ are phonemes, content figuræ are semantic units from which larger semantic units can be constructed (e.g., *man* would be formed by the content figuræ 'human,' 'male,' 'adult'). Content figuræ and expression figuræ are not in one-to-one correspondence: this is the reason why two planes are postulated (otherwise, such a postulation would be superfluous and the theory would violate the simplicity requirement). Any structure that has an expression plane and a content plane is named by Hjelmselv a semiotic, whereas structures with one plane only are 'symbolic systems.' Each plane can in its turn be constituted by a semiotic, and so on.

Structural Linguistics in France: Benveniste, Martinet

Émile Benveniste (1902–1976) combined his experience in the field of historical-comparative grammar of Indo–European languages with a particular skillfulness in the analysis of linguistic facts. He was surely well acquainted with the patterns of investigation worked out by European and American structuralism, but he resorted to them only to a limited extent. Somewhat paradoxically, this allowed him to sketch some analytical proposals that are sometimes superior to those of the structuralists. Among such proposals (see Benveniste, 1966), the most well known are his remarks on Saussure's notion of arbitrariness of linguistic sign and those concerning the definition and classification of grammatical persons and of pronouns, which parallel the investigations about performative utterances developed by Austin more or less during the same years (cf. Pragmatics section).

André Martinet (1908–1999) was in the 1930s, a foreign member of Prague linguistic circle; he consistently developed that 'functional view' of language explicitly stressed by the Prague theses (see Prague School section). Natural languages, in Martinet's view, have three features in common: (a) their communicative function, (b) their use of vocal utterances (i.e., natural language is essentially and primarily a vocal phenomenon, and only derivatively a written one), and (c) the double articulation, i.e., a first articulation into significant units ('monemes,' a term borrowed from Frei, but with a somewhat different sense, to replace 'morpheme'), which are in their turn articulated into distinctive units ('phonemes'). One of the most interesting instantiations of Martinet's functionalism is his investigations of diachronic phonology (cf. Martinet, 1955); the 'economy' of sound changes is the effect of the balance of two opposed tendencies, the 'minimal effort' (which tends to lessen sound differences) and 'communicative efficiency' (which tends to multiply them).

Other European Scholars (Guillaume, Tesnière, London School)

The scholars presented in this section, however, certainly influenced by Saussurean thought and hence ascribable to the structuralist trend, nevertheless remained somewhat aside from the debate that developed about the basic tenets of structural linguistics, especially between the two World Wars. This fact occurred also because the most significant works of some of them (e.g., Guillaume and Tesnière) were only posthumously published (see Guillaume, 1971–1990; Tesnière, 1966).

The writings of the French linguist Gustave Guillaume (1883–1960) are often difficult to read and interpret, especially because of the dark philosophical style that shows many influences. That by Henri Bergson (1859–1941) is especially significant in Guillaume's analysis of concept of 'time' (which he does not clearly distinguish from that of 'tense'). Among the several topics dealt with by Guillaume, one can quote his opposition between what is a formal expression in language ('psychosemiotics') and what is expressed by it ('psychosystematics'); only what has a morphophonological representation of its own can be called semiotic. Guillaume also proposed to replace Saussure's terminological pair *langue/parole* with *langue/discours* (speech). Speech necessarily presupposes language: their relationship

can be expressed in terms of the pair 'power' (language) vs. 'effect' (speech).

Lucien Tesnière's (1893–1954) work is especially important for its contribution to syntax. The seminal notion of Tesnière's syntax was that of valency. Tesnière compared the verb to "a kind of hooked atom" that can exert its power of attraction on a smaller or bigger number of 'participant roles' (*actants*). Besides participant roles, the sentence may also contain some 'circumstantial roles' (*circonstants*), which express the conditions of place, time, manner, etc., in which the process described by the verb takes place. Participant roles are obligatory; circumstantial roles are optional. The number of participant roles varies according to the verb class to which the verb belongs, so we have several verb classes according to their 'valency sets.' If Guillaume's linguistic thought did not exert any special influence on subsequent scholars, Tesnière's lies at the origin of several of the most important developments in syntax during the second half of 20th century (cf. Functionalist Schools section).

Among the linguists of the 'London school,' Daniel Jones (1881–1967) and John R. Firth (1890–1960) especially have to be cited. Jones was a phonetician deeply involved in practical questions (such as, for example, the assessment of the principles of phonetic transcription), but he also faced theoretical questions, such as the definition of phoneme. In contrast with the more abstract view held by Trubeckoj (cf. Prague School section), who defined phoneme on an exclusively linguistic basis, Jones opted for a 'physical' definition of phoneme as "family of sounds related in character no member of which occurs in the same phonetic context of any other member." Jones also rejected Trubeckoj's sharp opposition between phonetics and phonology.

Firth's view of language is characterized by the key role it assigned to the notion of context. He defined 'meaning' as 'function in context': not only words and sentences, but even phonetic units have meaning. Firth's contextual approach was especially fruitful in phonology. In his view, phonology cannot be limited to the segmentation and classification of sounds and phonemes ('paradigmatic units'), but must take into account also prosodic, 'syntagmatic' units such as the syllable (hence the name of 'prosodic phonology' given to Firth's theory). It is therefore necessary to study syllabic structure in terms of general sound classes, such as C(onsonant) and V(owel), and of their respective positions. Firth also maintained that grammar (i.e., syntax and morphology) and phonology are interdependent, anticipating in this way positions that will be later held in generative phonology (cf. Generative Phonology section).

Among Firth's students, one may cite R. H. Robins (1921–2000), especially for his historical researches on classical and medieval linguistics, and M. A. K. Halliday (b. 1925), whose 'Systemic Functional Grammar' (see Functionalist Schools section), worked out since the 1960s in successively revised versions, had several important applications in many fields, as artificial intelligence, discourse analysis, or language education.

American Linguistics from 1920s through 1960s

Sapir and His Heritage

American linguistics began to show peculiar features, different from those of European linguistics, from the beginning of 20th century. At that time, mainly because of the influence of the anthropologist Franz Boas (1859–1942), American linguists oriented a lot of their research to the study of Amerindian languages. Because such languages were devoid of written tradition, these scholars were automatically led to adopt a synchronic point of view. Furthermore, given the difficulty of applying the notions of Western grammar to such languages, attempts had to be made at describing them in purely formal ways: this led to the development of 'distributional' and 'classificatory' methods, i.e., based on the observation of pure occurrences of forms.

Edward Sapir (1884–1939) was himself an anthropologist and a linguist at the same time and devoted much of his research to Amerindian languages. His theoretical ideas are expressed in his book *Language* (Sapir, 1921), and in several papers posthumously collected (Sapir, 1949). According to Sapir, language is an 'overlaid function' from a physiological point of view, because it is a psychological and symbolic phenomenon. Hence, a purely physiological view of speech sounds, as was typical of late 19th-century experimental phonetics, is untenable: e.g., English *wh*-sound as in *when*, *where*, etc., is physiologically identical with the sound produced blowing out a candle, but the two sounds are essentially different, because only the linguistic *wh*- is 'placed' in a system that is composed "of a definitely limited number of sounds." In this way, Sapir arrived at a psychological conception of phonemes and variants.

Sapir's classification of grammatical concepts, on which his new approach to language typology is based, also deserves special mention. He classified them into two main groups: concepts that express 'material content' and 'relational' concepts. Each of both groups is further subdivided into two groups: so one obtains 'basic concepts' (1a), 'derivational

concepts' (1b), 'concrete relational concepts' (2a), and 'pure relational concepts' (2b). Concepts (1a) and (1b) are mainly semantically (or ontologically) based; they are 'objects,' 'actions,' 'qualities' (1a) and their derivations (1b). Gender and number belong to the group (2a), whereas grammatical relations (subject, object, attribute, etc.) belong to pure relational concepts (2b). The possible combinations of the four groups of concepts brings about Sapir's classification of languages into four 'conceptual types.' Type (A) languages only contain concepts (1a) and (2b); those of type (B), concepts (1a), (1b) and (2b); those of type (C), concepts (1a), (2a) and (2b); those of type (D), all four kinds of concepts.

Among Sapir's followers the important contribution of Morris Swadesh (1909–1967) to phonemics (a term that corresponds to the European 'phonology') is to be noted. The most well-known heritage of Sapir's thought is, however, the so-called Sapir–Whorf hypothesis, so called after his name and that of his follower, the nonprofessional linguist Benjamin L. Whorf (1897–1941). According to the theory, our vision of the world is heavily conditioned by our language. This hypothesis is today rejected, especially by those linguists, as generative grammarians, who maintain that cross-linguistic differences are actually more apparent than real. On the other hand, generative grammarians have often reevaluated Sapir's work against Bloomfield's, because of its psychologistic (or mentalistic) approach strongly avoided by the latter.

Bloomfield

Leonard Bloomfield's (1887–1949) behavioristic approach (see especially chap. 2 of Bloomfield, 1933) essentially consists of describing language as a chain of stimuli and responses (S-r-s-R): a speech event takes place when a nonlinguistic stimulus (S; e.g., hunger) produces a linguistic response (r) in the speaker (*give me something to eat!*) and such a response in its turn induces a linguistic stimulus (s) in the hearer, which has as a consequence the hearer's nonlinguistic response (R; e.g., providing food).

Bloomfield's major contribution to linguistics certainly does not lie in this crudely mechanistic view of language function, but instead in the working out of some analytical tools, particularly in the domains of morphology and syntax. The most influential of such tools is the so-called Immediate Constituent (IC) Analysis (see Bloomfield, 1933: chap. 13). In the classical example *Poor John ran away*, the immediate constituents are *Poor John* and *ran away*. The analysis goes on by partitioning *poor John* into *poor* and *John*, and *ran away* into *ran* and *away*. Furthermore, *away* is also analyzed into *a-* and *way*: the principle of immediate constituent analysis applies to morphology exactly in the same way as to syntax. IC analysis was subsequently deepened and formalized, not only by 'post-Bloomfieldian' linguists, but also within generative grammar.

Post-Bloomfieldian Structuralism

Linguists most directly influenced by Bloomfield's thought and analytical techniques especially developed the operational and distributional features of his conception of language. One of the most typical examples of this methodological trend was the so-called prohibition of mixing levels: phonological analysis must precede grammatical analysis and must not assume any part of the latter.

Among post-Bloomfieldian scholars, the following can be quoted, according to the different linguistic domains: concerning phonology, William F. Twaddell (1906–1982), Bernard Bloch (1907–1965), and George L. Trager (1906–1992); concerning morphology and syntax, besides Bloch and Trager, Eugene Nida (b. 1914); a very important intervention in the domain of IC-analysis is due to Rulon S. Wells (b. 1919); possibly, the leader of the group can be considered Charles F. Hockett (1916–2000), who dealt with all such different fields and also worked on theoretical problems, especially in polemics with generative grammar. The most original and influential among American structuralists is, however, Zellig S. Harris (1909–1992): in the1940s, he was engaged in the deepening and the formalization of Bloomfield's analytical techniques (see especially Harris, 1951); in the early 1950s, he worked out the notion of transformation. In Harris's framework, a transformation is seen as an equivalence relation between two different sentence-forms: e.g., *Casals play the cello* and *The cello is played by Casals*, or *he met us* and *his meeting us* are 'transforms' of each other. The notion of transformation (with important modifications) was to become a cornerstone of generative grammar, especially in its first phases (see later discussion).

Tagmemics and Stratificational Grammar

Tagmemics is the name given to the linguistic theory worked out by Kenneth L. Pike (1912–2000) and his associates and students. It combines both Bloomfield's and Sapir's insights, but it trespasses the boundaries of American structuralism in many respects. The Bloomfieldian side of tagmemics lies in its analytical techniques, which resume, deepen, and modify Bloomfield's. On the other hand, Pike's approach to language is decidedly and explicitly Sapirean:

language is seen as a cultural phenomenon, strictly tied to other cultural manifestations of human life.

Stratificational grammar was developed by Sydney M. Lamb (b. 1929) beginning in the late 1950s. It combines a post-Bloomfieldian approach with some European perspectives, mainly Hjelmslev's glossematics and Halliday's Systemic Functional Grammar. The number of assumed strata varies from two to six, according to the different versions of the theory. Mostly, four strata are assumed: semotactics, lexotactics, morphotactics, and phonotactics. Stratificational grammar aims at giving an account of all kind of linguistic processes, i.e., concerning both competence and performance (see later discussion): it shows, therefore, a 'cognitive' approach that sharply differentiates it from classical post-Bloomfieldian theories and makes it closer to generative grammar, although it is very distant from this latter theory both in the assumed principles and on many technical aspects.

The Beginnings of Typological Linguistics

Language typology was an important field in 19th-century linguistics, but was rather overlooked during the first half of 20th century, because Sapir's work on the topic remained an isolated exception. Things began to radically change in the 1960s, especially stimulated by the work of Joseph H. Greenberg (1915–2001). In Greenberg's perspective (see Greenberg, 1966), a close link is assumed between typology on the one hand and universals on the other. Language universals are no longer exclusively conceived as features that every language *must* possess: to such universals, named by Greenberg 'unrestricted' universals, also implicational universals and statistical correlations have to be added. The most well known instances of implicational universals concern the linear ordering of elements. Greenberg assumed as the bases of his language classification three possible choices: (1) whether a language has prepositions or postpositions ('prepositional' vs. 'postpositional' languages). (2) The position of the verb (V) with respect to the subject (S) and to the object (O). Of the six theoretically possible positions, only three normally occur: VSO, SVO, and SOV. (3) The order of the adjective with respect to the noun it modifies: A (=AN) vs. N (=NA). Such choices are systematically correlated with each other in an implicational way: this implication can be exceptionless or only statistically significant. An instance of the first case is the statement that if a language shows VSO order, it is *always* prepositional (Greenberg's Universal 3). On the other hand, Greenberg's universal 4 is an example of 'statistical correlation': if a language has a normal SOV order, it is postpositional "with overwhelmingly more than chance frequency." Greenberg's insights caused a tremendous development of typological studies, as will be seen in the Typological Linguistics section.

The Birth and Rise of Generative Grammar

The Origins of Generative Grammar

Generative Grammar (GG) is the label for the linguistic theory developed by the American scholar Noam Chomsky (b. 1928) and his followers; a GG, in Chomsky's own word, is "a system of rules that in some explicit and well-defined way assigns structural descriptions to sentences" (Chomsky, 1965: 8). Chomsky was a student of Harris (cf. previous section), but he early adopted a 'mentalistic' approach to the problems of language and knowledge, highly polemical against the behavioristic one, typical of Bloomfieldian and post-Bloomfieldian linguistics.

The first systematic version of Chomsky's theory appeared in print in a booklet called *Syntactic Structures* (Chomsky, 1957), which was partly an abstract of a much more voluminous work written in the years 1955–56 and published only 20 years later, with some modifications. The main features shown in this book with respect to the tradition of American structural linguistics were the following ones: (1) the goal of linguistic description is no more seen in the analysis of a given corpus, but in the accounting for the intuitions of the native speaker of a given language (well-formedness of sentences, synonymy, etc.). (2) A sharp distinction is traced between linguistic theory on the one hand and grammar on the other. (3) IC-analysis typical of American structuralism (see previous discussion) is formalized in a system of rules called Phrase-structure (PS) grammar. (4) PS-grammar is shown not able to adequately account for all sentences of any natural language. For example, it cannot account for the intuitive relation that any English speaker recognizes between two sentences such as *Mary gave a book to John* and *John was given a book by Mary*, or between the latter and *Who was given a book by Mary?* To account for such kind of relations, it is necessary to postulate a further level of rules, called transformations. This notion was borrowed from Harris, but it is rather differently conceived. Whereas, for Harris, it is a relation between *sentences*, for Chomsky it is a relation between *structures*. This means that the input of a transformation is a sentence in Harris' framework, whereas in Chomsky's one it is an abstract structure often rather remote from the actual sentence that it underlies. The importance given to the notion of transformation in the early phase of GG had the effect that Chomsky's

theory was initially known as transformational grammar rather than as generative grammar (actually, the use of the latter label was rather unsystematic at that time).

The Standard Theory

In the decade 1955–1965, the model of grammar described in the previous section was modified by Chomsky himself and by some of his early associates, such as Charles J. Fillmore (b. 1929), Jerrold J. Katz (1932–2002), Edward S. Klima (b. 1931), Robert B. Lees (1922–1996), and Paul M. Postal (b. 1936). The result of such changes was the so-called (by Chomsky himself) standard theory, presented in Chomsky (1965). The overall structure of the standard model is the following one: PS-rules and lexical insertion rules generate the deep structure both of simple and of complex sentences. The application of transformational rules to deep structure produces surface structures. PS-rules, lexical rules, and transformations form the syntactic component of grammar; deep structures are interpreted by the semantic component, giving the semantic representation of sentences; and surface structures are interpreted by the phonological component, giving the phonetic representation.

In Chomsky (1965), also the 'mentalistic' interpretation of linguistic theory, explicitly defined as 'part of theoretical psychology,' was maintained and argued for in detail. Chomsky opposed competence, defined as "the speaker–hearer's knowledge of his language," to performance, which is defined as "the actual use of language in concrete situations." The linguist has to discover "the underlying system of rules" (i.e., the competence) "from the data of performance" (Chomsky, 1965: 4). A grammar that correctly describes the competence of a native speaker of a given language is said to be descriptively adequate. A linguistic theory is said to be explanatorily adequate if it "succeeds in selecting a descriptively adequate grammar on the basis of primary linguistic data" (Chomsky, 1965: 25). The task of linguistic theory, then, becomes that of accounting for the properties of the LAD (Language Acquisition Device), i.e., the device that allows the child to construct a grammar from among a set of possible alternatives.

Generative Phonology

Generative phonology was discussed in several essays since the late 1950s and found its systematic presentation in Chomsky and Halle (1968). The starting point of generative phonology is that phonology is 'not-autonomous' from syntax: some phonological processes depend on morphological and syntactic structure. For example, the falling stress contour of *blackboard* is opposed to the rising one of *black board* because the former is a compound, hence belongs to the syntactic category N, whereas the latter is a Noun Phrase. Therefore the rules of assignment of stress contour must refer to syntactic surface structure (cf. Chomsky-Halle, 1968: chap. 2.1.). This is the reason why the phonological component is said to 'interpret' the syntactic component (see previous section). This strict interrelation assumed between the phonological and the syntactic level is quite contrary to the prohibition of mixing levels typical of post-Bloomfieldian structuralism (cf. section on this topic; Pike had already criticized this principle). Generative phonology considered the autonomous approach as a basic flaw of structuralistic phonology, both European and American, labeled 'autonomous phonemics': the notion itself of phoneme as conceived in such frameworks was rejected. Generative phonologists, on the one hand, took advantage from some difficulties in assigning which variants to which phonemes that had already been remarked upon within structuralistic phonology; on the other hand, they maintained that the assumption of an autonomous phonemic level often produces a loss of significant generalizations (the classical case was that of voicing of Russian obstruents, brought forward by Halle). Hence, generative phonology does not assume a phonemic level, but only a phonological representation and a phonetic representation. The former representation is derived from syntactic surface structure by means of readjustment rules; the latter is derived from the phonological representation by means of phonological rules, which apply in a given order. Both phonological and phonetic representations are strings of word and morpheme boundaries and of feature matrices. In such matrices, columns are segments, and rows indicate the value of features. Features of generative phonology only partly overlap with Jakobson's ones (see section on Prague School): their number is higher (about two dozen vs. 12 or 14), and they are mainly defined on an articulatory rather than on an acoustic basis. Features are 'by definition' binary at the level of phonological representation, whereas they are not necessarily binary at the phonetic one. An essential part of generative phonology is the so-called theory of markedness (developing, but also essentially modifying, insights of Prague phonology): features, segments and rules are not on the same plane, but some of them are more natural in the sense that they are more frequent, are acquired by the child earlier than others, etc. This greater or lesser naturalness is accounted for in terms of unmarkedness vs. markedness of the concerned entities and rules.

Since the 1970s, alternative approaches to the strictly segmental or linear model of Chomsky–Halle (1968) have been developed. For example, feature values and segments were no more seen as necessarily in one-to-one correspondence, but it was assumed that in some cases a single feature can extend over more than one segment, and, vice versa, a single segment can subsequently take two opposite values of the same feature (autosegmental phonology). It was also assumed that the domain of application of phonological rules is not only determined by the syntactic surface structure and readjustment rules, but also that the phonological representation has a hierarchic structure of its own, not necessarily coinciding with the syntactic one (prosodic phonology).

The Impact of Generative Grammar

Generative grammar (or, more exactly, generative syntax) aroused great interest among linguists shortly after the publication of Chomsky (1957). This interest became still greater in the subsequent decade, especially after the appearance of Chomsky (1965) and also reached logicians and philosophers of language. Generative tenets were not accepted by everybody: quite the contrary, many of them were sharply criticized. However, the large majority of linguists felt obliged to take a position on them. The following tenets were especially the focus of discussion: (1) The mentalistic view of linguistics (cf. The Standard Theory), which was later called cognitive. (2) The assumption that linguistic theory has to deal with 'an ideal speaker–hearer,' within a 'homogeneous linguistic community': i.e., the social and communicative aspects of language do not influence its structure. (3) The notion of Universal Grammar (UG), resuscitated by Chomsky (1965) with explicit reference to the tradition of *grammaire générale* starting with Port-Royal. From the early 1970s, UG essentially came to mean what he had earlier dubbed the 'language acquisition device' (LAD; cf. The Standard Theory): it was assumed to be universal since it would be shared by all human beings. (4) The postulation of two different levels of representation (deep and surface structure).

It is therefore possible to investigate the development of linguistic trends grown from the last 1960s according to the position they took with respect to the previously listed generative tenets. (1) Chomsky's cognitive view of linguistics was actually opposite the main structuralist trends, both in Europe and America, which conceived linguistics as an autonomous field. This new view was rejected, or at least dismissed as irrelevant, by some strictly formal approaches, such as Relational Grammar (see later discussion). It was, however, shared by the majority of trends during the last decades of 20th century, but often in a rather different way from Chomsky's. Indeed, although Chomsky simply assumed that to do linguistics *is* to do 'theoretical psychology,' many scholars maintained that linguistic explanations have to be traced back to more general psychological or cognitive factors, or, at least, they must be supported by independent psychological evidence. (2) Chomsky's low evaluation of social and communicative aspects of language contrasted with many earlier linguistic trends, even of the structuralist kind: e.g., Prague school defined language as a 'means of communication.' The view of language as a social phenomenon had been maintained at least since Meillet and it was strongly reaffirmed by scholars such as Uriel Weinreich (1926–1967) as an explicit rejection of Chomsky's views. Other opposition came from the pragmatic approaches to linguistic analysis that were developing within the philosophical tradition. More or less explicitly, all such trends opposed a 'social–communicative' view of language to the 'cognitive' one. (3) A revival of interest in the problem of linguistic universals had been already shown by researches such as Greenberg's; Chomsky's notion of UG clearly developed such interest in an unprecedented way. However, Chomsky's version of UG was not accepted by anybody: the different approaches to language universals were strictly linked with the different views of linguistics as a cognitive science and of relationships between language on the one side and social and communicative phenomena on the other. (4) Also the question of levels of representation was often linked to the problems of linguistic universals: several scholars equated 'deep structure' with UG, and 'surface structure' with cross-linguistic variation. These interpretations were misled, because both 'deep' and 'surface' structure had a specific technical value within a theoretical framework (see, e.g., Chomsky, 1975: 82). Nevertheless, they exerted a not negligible impact even on trends that were very distant from the Chomskyan one. Many of the debates between the different generative schools concentrated on the question if a distinction between whether a 'deep' and 'surface' structure is really necessary and on the nature of the 'deep' level.

In the following sections, trends stemming from generative grammar are distinguished from trends alternative to it. Such a distinction only refers to historical roots: the former trends were worked out by linguists originally (i.e., at the epoch of the standard theory) belonging to the generative group, the latter by scholars outside it. Nevertheless, several trends of the former group eventually became wholly alternative to the generative model.

Trends Stemming from Generative Grammar

Generative Semantics and Its Heritage

Generative Semantics (GS) was worked out between the 1960s and 1970s by scholars such as George Lakoff (b. 1941), James D. McCawley (1938–1999), Paul M. Postal (b. 1936) and John R. Ross (b. 1938). It was sharply opposed to the Extended Standard Theory (EST) by Chomsky and some of his followers. Both approaches shared a realistic view of linguistics and a multilevel approach to syntax, but their way of implementing such ideas was totally different. In their first works, generative semanticists rejected some basic assumptions of the standard theory: according to them, (a) deep structure was a useless concept, and (b) linguistic description must be semantically based. This semantic basis was sought in the reduction of linguistic categories to logical and/or psychological categories: semantic representation should be made to coincide with natural logic. In later works, it was assumed that semantic representation also includes typical semantic and pragmatic categories, such as focus or presupposition.

From the early 1970s, the leading ideas that had characterized the followers of GS were gradually abandoned, and each generative semanticist followed his own way. Lakoff first tried to work out a 'fuzzy' grammar, according to which grammatical categories are not discrete, but form a continuum from the noun at one end to the verb at the other. McCawley moved toward an empirical and somewhat skeptical approach to syntax: contrary to EST, McCawley kept on rejecting any theory of language acquisition that did not take into account general cognitive properties. From this point of view, Cognitive Grammar by Ronald W. Langacker (b. 1942) and his associates could be considered as a legitimate heir to Generative Semantics.

From the middle 1970s, two linguists formerly belonging to the GS group, David M. Perlmutter (b. 1938) and Paul M. Postal, developed a theory called Relational Grammar (RG). RG completely abandoned the notion of transformation as an operation on hierarchically and linearly ordered phrase markers. It also explicitly rejected any aim at being 'psychologically real.' RG takes grammatical relations as primitives and represents clause structure as an unordered set of constituents that bear grammatical relations to each other. Grammatical relations may change from one level ('stratum,' in RG terminology) to another. Strata are not connected by means of transformations, but of Relational Networks, which show which different grammatical relations the constituents bear at different levels.

Fillmore's Case Grammar was often associated to GS, but it is essentially independent from it, even if both approaches wholly replaced the standard notion of deep structure. In Fillmore's view, the 'basic structure' of the sentence consists of the verb and an array of case relationships (see Fillmore, 1968). By 'case,' Fillmore does not mean a morphological category, but an 'underlying syntactic–semantic relationship.' The elements of the basic sentence structure are unordered.

'One-Level' Approaches to Syntax

Generative Semantics pushed the distance between 'deep' and 'surface' structure to its extreme, by identifying deep structure with semantic representation. RG preserved a multilevel approach to syntax. From the middle 1970s, other linguistic trends originated that took the opposite path, giving up the distinction between deep and surface structure and assuming a single level of syntactic representation. The first systematic proposals in this direction are due to Michael K. Brame (b. 1944). The most successful of such 'one-level' approaches were, however, LFG (Lexical–Functional Grammar) and GPSG (Generalized Phrase Structure Grammar). LFG was initiated by Joan Bresnan (b. 1945), a former Chomsky graduate student, and GPSG by a British scholar, Gerald Gazdar (b. 1945), who was later joined in his research program by other British and American linguists. On the one hand, GPSG and LFG share several assumptions: e.g., both avoid transformations and resort to other techniques to solve problems that standard theory dealt with in transformational terms. On the other hand, they originated from and developed with rather different goals and concerns. LFG's original goal was the search for a 'realistic' grammar. GPSG was worked out mainly on the basis of formal concerns and had no special interest in building a 'psychologically real' grammar.

From EST to the 'Minimalist Program'

The syntactic theory worked out by Chomsky and his closest associates in the period from the late sixties until now had as its primary goal that of implementing the notion of Universal Grammar: the development of an adequate model of UG was seen as the proper goal of the cognitive view of language. This theory was called, during the 1970s, Extended Standard Theory (EST); in the 1980s, Principles and Parameters Theory (P&P) or 'Government-Binding Theory' (GB-Theory); from the early 1990s, the Minimalist Program (MP). Three works of Chomsky's could be considered the landmarks of each of these three phases: Chomsky (1973) for EST; Chomsky (1981) for P&P; and Chomsky (1995) for MP.

EST's main concern was the definition of restrictions on the functioning and on the format of syntactic rules. The first, decisive, step in this direction was the system of conditions on transformations of Chomsky (1973). More or less in the same period, Joseph E. Emonds (b. 1940) and Ray S. Jackendoff (b. 1945) formulated some important constraints on the format of transformational rules (Emonds) and phrase structure rules (Jackendoff). The great abstractness of all such conditions was assumed to be the proof that they could not possibly have been taught by adults or inductively discovered by the child. They were assumed to belong to Universal Grammar, namely the 'innate biological system' that is "invariant about humans" (Chomsky, 1975: 29). The innateness hypothesis, of course, contrasts with the actual cross-linguistic diversity. The Principles and Parameters approach was the first real effort made within the Chomskyan program to provide a systematic account of cross-linguistic differences. The universal features of language were dubbed principles, and the dimensions along which languages can vary, parameters. For example, the fact that a sentence in any language must have a subject would be a principle: but in some languages (e.g., Italian, Spanish, etc., as opposed to English, French, etc.) the subject may be 'null,' i.e., not phonetically realized. This option is called the 'null-subject-parameter': it has 'positive value' in Italian or Spanish, 'negative value' in English and French. Although principles are innate, the values of parameters are to be fixed on the basis of experience. 'Principles and Parameters' approach stimulated an amount of research much larger than anything previously done within any other framework connected with generative grammar. In particular, the notion of parameter stimulated cross-linguistic investigation of several languages.

Chomsky, however, was more interested in the depth than in the breadth of explanation (in a sense, more to explanatory adequacy than to descriptive adequacy) and since the early 1990s developed the 'Minimalist Program.' The leading criterion of MP can be considered that of economy, namely resorting to the least possible number of entities and of levels of representation. Therefore, MP disposed of the levels of 'deep' and 'surface structure' and assumed Phonetic Form (PF) and Logical Form (LF) as the only levels of representation. Nevertheless, MP cannot be equated with 'one-level' approaches discussed in the preceding section. In fact, also this last version of Chomskyan generative syntax essentially assumes a very abstract relation between the phonetic and the semantic side of language: PF and LF are related by the computational system, i.e., a transformational apparatus. One of the main goals of MP is just to show *why* transformations exist: *prima facie*, they would seem to be antieconomical. The answer is that they exist to replace uninterpretable features, which are also antieconomical: by so doing, both imperfections erase each other. Natural language is therefore a perfectly economical system, and from this point of view, Chomsky maintains, it is very rare among other biological systems.

Trends Alternative to Generative Grammar

Functionalist Schools

The common feature of functionalism is the assumption that language structure is conditioned by its function as a means of communication. This approach was already taken by some structuralist scholars, such as Martinet, and especially the founder of Prague school, V. Mathesius, who distinguished between the formal (i.e., the grammatical) and the actual (i.e., the communicative) partition of the sentence. Mathesius's insights were taken over by Prague linguists of the subsequent generation, such as František Daneš (b. 1919) and Jan Firbas (1921–2000), who coined the term Functional Sentence Perspective to mean Mathesius's actual partition.

From the 1960s, the most significant functionalist schools developed as an explicit alternative to the formal paradigm of generative grammar: Functional Generative Description (FGD), mainly worked out by Petr Sgall (b. 1926) and his associates, which represents a further stage of Prague School linguistics; Simon Dik's (1940–1995) Functional Grammar (FG) and Halliday's Systemic Functional Grammar (SFG). FGD proponents did not reject generative grammar as a whole, but maintained that it was too partial as an approach to language; on the other hand, they considered exclusively pragmatic approaches to be partial as well.

Despite their differences, all these functionalist schools share an important common core, the main points of which are the adoption of (a) Functional Sentence Perspective, and (b) a kind of Tesnière's valency grammar, in its original form or mediated through Fillmore's Case Grammar. Hence, their fundamental problem was to work out a device to explain the relationship between the system of Tesnière's roles (or Fillmore's 'deep cases') and the grammatical and communicative organization of the sentence.

Typological Linguistics

Typological linguistics since the early 1970s, mainly developed as an attempt to explain word order

correlations stated by Greenberg (see the section titled 'The Beginnings of Typological Linguistics'), and it gradually replaced purely syntactic explanations with semantically and pragmatically based ones. It is therefore independent from generative grammar both in its origins and in its achievements. However, some insights stemming from generative grammar influenced typological studies, especially in the 1970s. For example, Winfred P. Lehmann (b. 1916) started from a syntactic model analogous to that of Fillmore's Case Grammar. He assumed an unordered 'underlying structure,' to be converted into a linearly ordered one by a rule with phrase-structure format: therefrom VO-languages vs. OV-languages would result (cf. Lehmann, 1973).

The most significant development of Greenberg's proposals about word order universals is due to John A. Hawkins (b. 1947), who showed that cases that appear as exceptions in Greenberg's treatment are actually not exceptions, if Greenberg's universals are reformulated in a 'complex' form. An example of such reformulation would be the following: "if a language is SOV, then, if it has AN order, it has also GN order" (cf. Hawkins, 1983: 64).

Two other key notions developed in the framework of typological linguistics, especially by Edward S. Keenan (b. 1937) and Bernard Comrie (b. 1947), are continuum and prototype: categories are no more defined, as in generative grammar, in terms of possessing or not possessing a given property, but as clusters of properties. If all such properties occur, the concerned category is 'prototypical'; the deviations from the prototype are distributed along a 'continuum.'

Sociolinguistics

The label 'sociolinguistics' was firstly used in 1952 by the American Haver C. Currie (1908–1993), but it became widespread from about the late 1960s. In the last decades, this label ended in indicating a variety of researches, both of theoretical and applied kind, from 'ethnography of speaking' to 'language policy.' Between the 1960s and the 1970s, however, a sociolinguistic trend presented itself as an alternative approach to generative grammar.

The leader of this trend undoubtedly was William Labov (b. 1927), to whom the notion of variable rule is due. Variable rules have the format of PS-rules of generative grammar (more exactly, of *context-sensitive* PS-rules): their application or nonapplication, however, is not *categorical*, but it is conditioned by some probability factors, both of linguistic and extralinguistic (i.e., social, stylistic, regional) kind. By resorting to the device of variable rules, Labov was able to account for the different realizations of the same grammatical phenomenon across different social groups (a paradigmatic case was that of the contraction vs. deletion of the copula *be* in white vs. black American English speakers; see Labov, 1969).

The status of variable rules became a topic of intensive discussion. Do they belong to competence or to performance? Labov initially assumed that they are part of competence, but he eventually (in the 1970s) rejected the usefulness of such distinction. On the other hand, a radical revision of Chomsky's notion of competence had been proposed in 1968 by Dell Hymes (b. 1927), who replaced it by that of communicative competence, which indicates the speaker's ability to use language according to the different social and contextual situations. It can be remarked that, since the EST period, also Chomsky referred to a 'pragmatic competence' interacting with the grammatical one. Hence, the problem is whether grammatical competence is independent or not from 'pragmatic' or 'communicative' competence: Chomsky's answer was affirmative, whereas that of sociolinguistics and pragmaticists, negative.

Pragmatics

From the 1960s, pragmatics presented itself as an alternative to the Chomskyan view of language as a cognitive capacity fully independent from its use. Indeed, the roots of pragmatics lay earlier than generative grammar: the term had been created in 1938 by the philosopher Charles W. Morris (1901–1979) and the research field had as its initiators, between the 1950s and the 1960s, two British philosophers of language, John L. Austin (1911–1960) and H. Paul Grice (1913–1988) (neither of whom, however, used the word *pragmatics*). Austin maintained that speech is action (cf. Austin, 1962). The primary evidence for this is given by the utterances called performative by Austin, such as *I promise you to come*, by means of which I am not only *saying* something, but also *doing* it. Performative utterances are a kind of illocutionary act: examples of illocutionary acts are question, order, etc. According to Austin, a speech act, besides the illocutionary act, consists of the locutionary act (the uttering of given words and phrases) and the perlocutionary act (the intended effect of the speech act on the hearer). This classification of speech acts was partly revised by John R. Searle (b. 1932).

The original motivation of Grice's 'logic of the conversation' (which dates back to essays from the 1950s, eventually collected in Grice, 1989) was to show that there is no real divergence between the meaning of symbols such as $\sim$, $\forall$, $\exists$, etc., of formal logic and their counterparts *not*, *all*, *some*, etc., in natural language: the apparent differences of meaning are due to certain principles governing conversation, the conversational maxims. If I utter a sentence such

as *Some students passed the examination*, I am undoubtedly saying the truth, even if *every* student did in fact pass the examination, but the hearer normally interprets it as meaning that only some students, and not all of them, passed the examination. This is due to the fact that I have violated the 'maxim of quantity': "make your contribution as informative as is required" (cf. Grice, 1989: 26). From my violation, the hearer has drawn the conversational implicature that only some students, and not all, passed the examination.

The analysis of speech acts and of logic of conversation are still today at the center of interest of pragmaticists. The interest in conversation also made pragmatics include a good deal of text linguistics, which originally started as a project to extend formal techniques of generative kind to units larger than sentences. In recent decades, text linguistics seems to have been replaced by the more empirical and informal conversational analysis, initiated by sociologists such as Harvey Sacks (1935–1975) or Harold Garfinkel (b. 1929), but later adopted by pragmatics-oriented linguists.

Two-Dimensional Semantics

C Spencer, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

When we ask whether a sentence is true or false, we are always asking with respect to a particular world. We are typically concerned about a sentence's truth value in the actual world, but we sometimes consider its truth value in other possible worlds as well. Thus the evaluation of any sentence is world-dependent in the sense that whether it is true (in a world) depends on the facts about that world. Context-sensitive sentences are also world-dependent in another quite different sense – what they mean depends on facts about the context, or world, in which they are used. For instance, *it's cold here* uttered in Pakistan means that it is cold in Pakistan, and when uttered in New Jersey means that it is cold in New Jersey. Two-dimensional semantics uses a formal apparatus from two-dimensional modal logic to characterize these two kinds of world-dependence. The two-dimensional framework has been applied to a variety of problems in semantics (indexicals and demonstratives and their interaction with modal operators), pragmatics (presupposition), and philosophy (accounts of the *a priori/a posteriori* distinction and the psychological/functional roles of thought). All of these applications depend on various assumptions, which are not implicit in two-dimensional modal logic, and many of which are controversial.

Modal logic allows that expressions may have different extensions in different possible worlds. For instance, it allows that the objects that satisfy a predicate in one world may differ from those that satisfy it in another. In one-dimensional modal logic, the rule that determines each expression's extension in every world, called its intension, is represented as a function from possible worlds into extensions. The intension of a predicate F, for instance, is a function that takes a possible world onto the set of individuals that satisfy F in that world, and the intension of a singular term *t* is a function taking possible worlds to single individuals. Two-dimensional modal logic allows that a single expression may be associated with different one-dimensional intensions in different contexts, or worlds, of use. So it associates a two-dimensional intension with each expression, which is a function from possible worlds to one-dimensional intensions, or equivalently a function from ordered pairs of possible worlds into extensions (see Segerberg, 1973; Aqvist, 1973; van Fraassen, 1977 for expositions of a two-dimensional modal semantics for formal languages).

Since a two-dimensional intension takes pairs of possible worlds onto extensions, it has the resources to represent the two different kinds of world-dependence mentioned above. One of the worlds supplies the contextual elements needed to interpret context-sensitive expressions, and the other world supplies the context of evaluation. I will call the entity that plays the former role the world of occurrence, and the entity that plays the latter role the world of evaluation, although no terminology is standard.

Two-dimensional intensions can be represented in a matrix such as **Figure 1**, which gives a two-dimensional intension for a single expression, *s*. In the leftmost column of **Figure 1**, w^1, w^2, and w^3 represent possible worlds considered as worlds of occurrence. In the top row, these same three worlds are considered as worlds of evaluation. Suppose that *s* is the sentence *I am in San Francisco*. In w^1, Ann is the speaker of this sentence and Ann is in San Francisco. She is also in San Francisco in w^3, but not in w^2. In w^2, Beth is the speaker, but she is in London in all three worlds. In w^3, Carl is the speaker, and Carl is in San Francisco in all three worlds. The cells of this matrix are filled in with truth values, since this is the appropriate extension for sentences. The row corresponding to w^1 tells us the truth value, in w^1, w^2, and w^3, of the sentence *s*, considered as occurring in w^1. In w^1, Ann utters this sentence, so it is true just in the case where Ann is in San Francisco. Accordingly, this occurrence is true in w^1 and w^3, but false in w^2, as the matrix indicates. Similarly, the row

s	w^1	w^2	w^3
w^1	T	F	T
w^2	F	F	F
w^3	T	T	T

Figure 1 Two-dimensional matrix.

Literacy Practices in Sociocultural Perspective

J Collins, University at Albany, SUNY, Albany, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

This article discusses some of the things meant or intended when researchers refer to 'literacy practices.' One meaning is that the researchers will treat literacy as an event in which the (arti)facts of inscription cannot be separated from persons, settings, and other communicative modalities. In addition to this descriptive aim, the term also usually signifies a theoretical ambition. Across multiple disciplines of social inquiry, reflecting the legacy of thinkers such as Sahlins, Williams, Foucault, Giddens, and Bourdieu, the term 'practice' has come to signify a range of theories and frameworks that grapple with the interplay of structure and construction, history and agency (Ortner, 1984). Although a literacy event may be as personal and fleeting as jotting down a list or glancing at an advertisement, literacy understood as the making or interpreting of inscriptions has a history of many millennia, and is closely associated with long-term and large-scale enterprises, such as cities and states, armies and schools, extensive markets and world religions. Relating the personal to the large-scale, the fleeting to the enduring, subject to structure, is thus a challenge confronting the study of literacy practices.

The term 'New Literacy Studies' (NLS) denotes a broad framework, drawing together various critical approaches within the field of literacy studies, consciously built upon the notion of literacy as a **practice**, rather than, say, a psychological skill or abstract social property. Within the NLS framework, literacy practices have been explicitly discussed as entailing a twofold research intention: (a) to build upon the notion of literacy as a communicative event, itself derived from the anthropological ethnographies of communication paradigm, but also (b) to push analysis beyond events to the ideological framing and institutional contextualizing that gives particular events their broader significance (Street, 1993). In this effort, NLS work has drawn particular inspiration from the ground-breaking research of Shirley Heath on literacy events, and it has used the anthropological notion of 'cultural model' to explore relations between consciousness and institutions. It has also, however, been informed by European and English traditions of critical discourse analysis, which call for the study of language as a social practice, an approach to language/society informed by Marxian analyses of ideology and hegemony and Foucault's arguments about discourse, knowledge, and power (Rogers, 2003).

In what follows, I first discuss work in the latter 'New Literacies' (NLS) framework, then indicate amplifications and framings suggested by sociocultural perspectives drawn from anthropology and linguistic anthropology (LA), arguing that the differing approaches only partly overlap. The article concludes by addressing contemporary literacy problems in the US and the complementary strengths and weaknesses of the two approaches (NLS and LA) in thinking about those problems as well as in providing frameworks for more general understandings of the phenomena of literacy and practice. It goes without saying, an article of this scope will unavoidably be schematic, citing only directly relevant work, leaving much that is worthwhile unmentioned and treating as settled much that deserves further argument.

Literacy Practices in the New Literacy Studies

As noted above, within the NLS approach, priority is given to studying literacy events, the situated doings that involve acts of reading, writing, or both. Highly influential early work was that of Heath (1983), who showed that in home, school, workplace, or church, what was a issue was not a binary contrast between literacy and orality, but rather the socially situated and culturally mediated events – whether reading a bedtime story or reading the mail, filling in a job application or composing a prayer for a church service. Participating in such events, people not only decoded or encoded text but were socialized into and enacted particular views of what reading or writing might be, who took what roles in such events,

and how they were part of larger-purpose endeavors: bringing up children, going to school, getting and keeping a job, expressing faith. In calling attention to the fact that acts of inscription and interpretation were part of a more general communicative economy, Heath's studies were part of a more general inquiry, also undertaken by historians and literary scholars, into the relations between orality and literacy (see Gee, 1996, for one review).

With the breaching of boundaries between written text and spoken event, the question of context is sharply raised, or in a more specific analytic idiom, the issue of indexicality is posed. Shuman (1986), in an in-depth study of working-class girls' "fight stories," emphasized that the right or authority to provide an account (that is, to be or not be talking behind someone's back, itself grounds for an altercation) depended on particularities of relationship and situation, not on the communicative modality of speaking or writing *per se*. Drawing upon work by Garfinkel and Sacks, she noted that "all utterances are indexical . . . [that is,] all utterances have multiple possible meanings and any particular meaning is **an understanding of context** (Shuman, 1986: 119, emphasis added)." Arguing that the principle of indexicality extended to inscribed utterances, she argued that "The recognition of indexicality admits the possibility of multiple interpretations of text (Shuman, 1986: 120)." The theoretical recognition of indexicality, and the practical possibility of multiple interpretations of text, means that there can in principle be no strict line between text, context, and interpretation. The point is not simply that multiple interpretations are possible, which is true but uninteresting in itself. Rather, it is that which interpretations gain authority is a matter of social dynamics, involving actors and institution-based understandings, as well as inscriptions.

The second aspect of the NLS understanding of literacy practices is that practices necessarily involve a cognitive-ideological dimension – of cultural models and implicit theories regarding what counts as reading or writing. One of the more systematic treatments of literacy models, Bialostok (2002), analyzes interviews with a set of middle-class parents, arguing for a "white middle class model of reading," in which the reading of prose (fiction or non-fiction) in books is given near-exclusionary status. In Bialostok's analysis, the statements that interviewees make, such as "Reading is part of me" or "I can easily gorge down a novel a day," are expressions of metaphors which **indirectly index** a cultural model in which reading is a proxy for morality (Bialostok, 2002: 351). In this model, reading is recurrently talked about as a moral act of worthy consumption, and a series of interesting metaphors are attached to this textual consumption. Book reading is sustenance, it fills readers up; indeed, they can 'devour' or even 'binge' on books. Reading books is a fitting part of the good person: "Books fit in with my life," says one respondent; "Reading is something that's just part of me," says another (Bialostok, 2002: 356). The person who doesn't read (books) is often characterized as "missing a lot of things" (Bialostok, 2002: 357). Book reading produces economic well-being: "Books have enriched our children's lives" says one respondent. But its lack points to poverty: "It's just so sad when a child doesn't have any books or isn't read to. They have such impoverished lives," says another interviewee (Bialostok, 2002: 359). As Bialostok argues, this is not just a matter of variation in culturally specific conception of reading, coherent and articulated through interlocking images, and anchored in the institution of the middle class family. It is also that this is the model or theory of reading promoted by the child-rearing professions of the contemporary US and, in particular, the school. It is a model that recognizes and gives legitimacy to certain class-associated literacy practices, while ignoring or derogating acts rooted in other systems of value (see also Heath (1983)).

An important point about positing what we might call an ideological level of models and implicit theories that are part of literacy practices is that, as with language ideologies more broadly, such conceptions and theories mediate between real-time micro-interactional events, and institutional orders, that is, perduring social classifications, organizational forms, and activity types. In his ethnography of literacy on the Pacific atoll of Nukulaelae (Tuvalu), Besnier (1995) shows that letter writing gains its full significance within a configuration linguistic, cultural, and social features that include Nukulaelae lexical and grammatical categories of affect, norms for face-to-face conversation, norms for gender-based emotional expression, and extensive labor out-migration. Most pertinent to our current theme, Besnier shows that the strong evangelical religion practiced on the island provides weekly enactments, through sermons, of gendered personhood and authority.

In Besnier's account, Nukulaelae sermons feature a blending of literate and oral resources: sermons are written beforehand, but preaching styles draw on other ritual genres as well as biblical passages. For many Nukulaelae, sermons are key events in which religious authority and a public search for truth is performed, displayed, and claimed. The sermon is part of a more general fundamentalist epistemology: " . . . Scriptures are the ultimate arbiter of truth. If they abide by the authority of God and the Bible, humans

can gain access to the unambiguous truth that is otherwise beyond their reach (Besnier, 1995: 141)." This pursuit of truth is done by individuals evoking and commenting upon the sacred scripture in written sermons: "[the composition and performance of which] centralize an individualistic sense of personhood and the search for the truth (Besnier, 1995: 138)." But the sermon is part of – that is, it reflects, expresses, and reproduces – an institutional hierarchy of gender and knowledge: though women as well as men may preach, only men can write a sermon.

That conceptions of reading or writing include assumptions about categories of person appropriate to a given activity is, of course, not surprising. The exclusion of women from Koranic or Talmudic scholarship is well known; enlightenment intellectuals in Europe and Colonial North America assumed that Blacks, whether free or enslaved, were incapable of writing; and in pre-Revolutionary America, it was normative that the virtuous woman should read, but not "take up the pen," especially for public expression (Warner, 1990). Such ideological framing of literacy events, combining cultural classification (e.g., male/female, white/black) and institutional site (e.g., the school, the pulpit, the press), shows that concepts of literacy practice must extend beyond the observable event.

Literacy Practices in Sociocultural Perspective

The New Literacy Studies has been largely an undertaking of educators, anthropologists, and sociolinguists who have successfully critiqued earlier claims about literacy as a context-independent "technology of the intellect" and called into question many school-based and official definitions of literacy (Street, 1984; Gee, 1996). As a research program it has, however, been less successful in areas germane to a sociocultural perspective on literacy practices. These areas include the following: (a) registering the consequences of the artifactualization of language wrought by inscription and the technical-institutional distribution of such text-artifacts, (b) analyzing the ideological range that accompanies literacy endeavors in comparative, global perspective, and (c) attending to institutional and social structural influences on literacy practices outside contemporary Western states and school systems. I address each of these themes below.

Artifactualized Language

One undeniable aspect of inscription is that it turns language into a thing, it renders some element of language (words, syllables, phonemes) into an artifact, into marks made in some medium (clay, papyrus, paper, acetate). These artifacts can, in turn, become input for procedures of accumulation and distribution of varying scale. Despite the untenability of Jack Goody's general conception of literacy, one value of his extensive research is his emphasis on procedures of accumulation and distribution of text-artifacts as essential processes in the evolution of social complexity. In what is otherwise a critical assessment of Goody's 1986 monograph, *The logic of writing and the organization of society*, Collins and Blot (2003: 20) have written:

> A general virtue of *LWOS* is that it provides constant reminders of the semiotic dimensions of social complexity. An endless keeping of lists seems to accompany social undertakings of any significant scale: censuses of population undertaken by states and lists of priest-officiants maintained by temples are prime examples. Bookkeeping emerged early as a primary function: if not *the* primary function of inscription in Mesopotamia, and it figured in subsequent temple, palace, and merchant economies in the Ancient Near East.

As if in complement to Goody's *The logic of writing and the organization of society*, Olson (1994) developed an extended inquiry into philosophies and practices of reading in the intellectual traditions of Western Europe. He argues that a written textual representation is important because as an artifactualizing of language, it suggests **a** model of language. This model inclines users to become (a) aware of the dimensions of language represented (say, letters or words) and (b) troubled by what is **not** represented, that is, by what is left unsaid. In Olson's account, an historical confluence of ideological, institutional, and technological developments in Western Europe results in a general model of reading-faithful-to-the-text, which arose out of medieval and early modern religious debates, was given substantive diffusion by the development of universities, printing and print-capitalism, and entered into debates in 16th- and 17th-century science about how to best read the *Book of nature*. As articulated by Francis Bacon and other early modern philosopher-scientists, the model of reading became part of a doctrine of truth based on precise records, in "unadorned style," in experimental and other natural scientific inquiry. This concern for realistic, replicable representations of the natural world, in turn, gave impetus to developments in various representational media which flourished in the 17th–19th centuries: portrait painting, map-making, and botanical drawing. These representation media themselves became print artifacts, mechanically reproduced, extensively distributed, and mediating far-flung engagements in a world being transformed by capitalism and colonialism.

What is often called 'the print revolution' was a central element in the production and distribution of artifactualized language. Historians of print (Eisenstein, 1968) have described the cultures of print emerging along with the new technology developed by Gutenberg in Germany in the 1450s, and they have described the very rapid spread of both production sites and book artifacts. As noted in Crosby's (1997) suggestive analysis of the role of measurement and representation in European science and technology: "By 1478 they were printing in London, Cracow, Budapest, Palermo, Valencia, and a number of cities in between. By the next century millions of books had been printed (Crosby, 1997: 231)."

The widespread diffusion of print artifacts, and especially books and newspapers, gave rise to new ways of viewing language, space, and time, encouraging, in turn, new ways of imagining both collectivities and individual nature. For Eisenstein, what she called "the uneven rise of reading publics" led to new forms of individual development. She argues that with the spread of books, lives became more procedure-bound as individuals and groups began "going by the book" (Eisenstein, 1968: 39). Such "going by the book" was a textual ethos and practice characterizing a "'middle class' secular puritan" ethos found in Protestant Europe and North America, in which domestic handbooks, marriage guides, and etiquette rule books were paramount in the conduct and judgment of lives. Eisenstein suggests that the new literate individualization also contributed to the envisioning of and identifying with new collectivities, in particular, the nation-state.

This line of argument has been influentially developed by Anderson (1991), who argues that wide dissemination of newspapers and novels provided textual materials for imagining new spatial and temporal orders, for which the language-codifying nation-state was both instrument and outcome. A more historically and culturally nuanced account of such processes is provided in Warner's (1990) analysis of letters, literacy, and political categories in late colonial and early national U.S. history. In his account, foundational concepts such as 'citizen' are linked to social divisions – such as those between men and women, whites and blacks – and to particular textual practices, such as collecting personal libraries, practicing journalism, and selling an 'American literature.'

We now live of course in an era not of ascendant nationalism but of globalization, wrought not by printing press but by computing machines and their communicative infrastructure. Space considerations do not permit much discussion, but there has been considerable interest, debate, and writing about this most recent development in the production and distribution of text-artifacts. We need not need enter the debates of whether the digital technologies are revolutionary newcomers, or merely new communicative modalities interacting with older modes, whether they herald an era of dystopian or utopian postliteracy (Warschauer, 1999). But we should note that with digital as with alphabetic literacy, artifactualized language provides ways of mediating communication, channeled through existing and emerging institutional forms, typically with official inducements for appropriate use and sanctions of inappropriate use, and typically also accompanied by an underground of subversive, wayward practices.

Sociocultural Practices of Language Use Associated with Inscription and Artifact Circulation

In the preceding section I focused upon the artifactualizing of language brought about by inscription, some of the major developments in the production and distribution of such artifactualized language, and some of the historical, institutional, and psychological developments associated with these communicative economies. These latter include the rise of states and general religions, the development of science, nationalism, and the rule- (or book-) bound self. It is ethnocentric and crudely techno-deterministic to argue, as some have, that the alphabet, *qua script*, causes modern science. I agree with Brandt (2001), however, that the many students of literacy practices have gone too far in denying a technical dimension to literacy, giving short shrift to technical–institutional interactions and political economic dynamics in the history of literacy.

This concern registered, it is also important to stress that there are always cultural variations in the way literate resources are taken up and put to use. Indeed, to its credit, the NLS framework has always stressed such variation. Given its concern to critique official, dominant understandings, it has not, however, brought out the playful, subversive uses of literacy; such transgressive uses often highlight the cultural shaping of literacy practice.

Burke's (1988) 'The uses of literacy in Early Modern Italy' gives a picture of literacy practices in a flourishing mercantile city state. Not surprisingly, we learn that in the 16th-century city state of Florence there was a robust notarial culture in which merchants kept extensive accounts and engaged in voluminous correspondence as they tracked expenditures and profits over far-flung trade networks. Also not surprisingly, we learn of secular, sacred, and patriarchal efforts at regulation: the Florentine state pioneered the use of written passes in order to regulate

subjects' travel; the Church issued tickets that were collected at communion, part of a record book registering attendance and nonattendance; and literate Florentine males proposed what Burke calls a "rule of female illiteracy (Burke, 1988: 38)." This latter prohibition on who should read and write seems to have been caused by a familiar patriarchal plight: fear of wayward female sexuality, more particularly, that literate wives and daughters might get up to no good by trafficking in love letters. The state, for its part, feared unauthorized reading of its correspondence and pioneered the use of ciphers for encrypting correspondence. The Counter Reformation Church was troubled by both literacy and **il**literacy. Literates were problematic because they might read heretical works, such as those being busily produced and disseminated by Protestant printers to the north. Illiterates, on the other hand, were worrisome because they were fond of and susceptible to superstition and magic. And the illiterate majority of early modern Florence had access to **written** magic: spells, incantations, and medical cures that used alphabetic sequences (such as *abracadabra*), printed and otherwise inscribed on cards, amulets, and other objects, in order to evoke and control the supernatural.

There is a small but interesting body of research showing that in colonial and postcolonial settings, hybrid forms of spiritual practice involve non-Western peoples appropriating the idea of supernatural powers of sacred text. This is the case among the Mende of Sierra Leone, who make spells and talismans with fragments of Classical Arabic (Koranic) script (Bledsoe and Robey, 1993); it is also the case with the Gapun villagers of Papua New Guinea, who manipulate Biblical text in search of the material benefits promised by Cargo religion (Kulick and Stroud, 1993). Basso's (1990) description of an indigenous Apache writing system reports the case of Silas John, a mission-raised Apache who in early adulthood experienced visions in which God apparently imparted knowledge of 62 prayers and a system for writing them down. The writing system was novel in form, drawing upon both English orthography and Apache sand-painting designs. After his visions, Silas John became the prophet of a neotraditionalist religious movement, gathering a select band of twelve disciples, to whom he taught his system of writing. He and his followers then used the writing system to record prayers and other instructions for use in rituals. In short, Silas John drew upon the idea of the power of **divine writing**, creating a written code, knowledge of which was necessary to successful performance of ceremonies. A traditional practice of rites was continued, but only through the agency of new literates, readers who controlled access to the divine through their manipulation of esoteric script. A case strikingly similar to this one, and roughly contemporaneous, is that of the Aladura movement in colonial Nigeria during the 1920s. It also involved a prophet, Oshitelu, who also received prayers in a vision, along with a writing system for recording them. Oshitelu's writing system was distinct from English orthography, in which this prophet had also been schooled, and thus was accessible only to the specially trained (Probst, 1993).

In a recent study of practices of magical writing in Highland Ecuador, Wogan (2004) describes how the villagers of Salasaca attribute life-threatening power to acts of writing and erasure. Wogan argues that many practices of magical writing are a mirror-image of the Ecuadorian state's concern to record all indigenous peoples in its Civil Registry. In a campaign advertising the need to register new births, the slogan *Si el niño no está inscrito, es como si no existiera* ("If a child is not registered, it's as if he doesn't exist") is proclaimed on posters and television (Wogan, 2004: 52). Conversely, Salasacans attribute life-threatening power to placement of a name in the book of San Gonzalo, a local saint. Hence the mirror-image: if a child's name is not registered in one book, the Civil Registry, it is "as if" he or she does not exist; if a name of a person is placed in another book, that of San Gonzalo, that person is in mortal danger, until they have their name removed (which erasure eliminates the supernatural threat).

Ideologies of Language and Literacy

As should be apparent from the foregoing discussion of religious and magical literacy practices, the existence of text-artifacts and their use in specific local settings is often overlain with a strong evaluative dimension, that is, an ideological layering. The view that a letter, a word, or a name or a passage in a book gives access to supernatural beings and powers is a belief, an idea about language, and an element in a framework for relating practices with language artifacts to concerns at once worldly and otherworldly. The idea that some given language or form of language has special powers is widespread, and the so-called world religions are well-known for their linguistic orthodoxies. I will illustrate two cases. For Muslims, Classical Arabic is the only language in which the holy Koran may appropriately appear; for Roman Catholics, until recent decades, Latin was the only correct language for the liturgical service. Aspects of this religious belief in the divine nature of specific languages clearly recurs in the nationalist equation of "a (n artifactualized and print-disseminated) language and a people," an equation of essentialized language and political-cultural

community, which has informed political struggles and education policy throughout the world (Anderson, 1991; Bauman and Briggs, 2003).

Sometimes the focus of ideological reasoning is not language *per se* but the particular script in which the divine is both evoked and represented. This is apparent in the Apache and Nigerian cases described by Basso and Probst. Such cases in turn reflect a more general state of affairs: that orthographies (systems of inscription) are never neutral phenomena. They are instead often the object of sharp controversy over the best (i.e., the most authentic or scientific) way to represent a given language. The varied conflicts and their constituencies, sites, and orthography-ideas are discussed in research on language revitalization movements in Europe, South Asia, and the Americas (see, for example, the papers in Fenigson, 2003).

In a more abstract fashion, thinking about literacy has incorporated specific assumptions about orthographic development and social evolution. Goody and Olson, for example, put forth claims about an "alpabetic mind" as part of arguments about the supposed superiority of alphabetic over other writing systems. Such claims were quickly refuted by anthropologists and comparative psychologists (see Street, 1984, for a general review), but they reflect an old legacy in Enlightenment thinking about literacy and society. Rousseau, in his writing on the social contract, posited an equivalence between kinds of inscription and stages of society. The scheme went like this (see discussion in Collins and Blot, 2003: 166–167):

- Savagery (non-state societies) = Picture writing
- Barbarism (non-Western Asiatic states) = Hieroglyphic writing
- Civil Man (Western states and empires) = Alphabetic writing

This evolutionary hierarchy recapitulates other now-discredited hierarchies of culture, thought, and language, but with a focus on orthography rather than grammatical form.

In yet other cases, it is neither a given language or script that is central to the ideologizing of literacy practices, rather it is the encounter between a superposed world language/religion and local beliefs about both language and the supernatural, resulting in novel construals of uses of artifact-language. This is the situation reported by Kulick and Stroud (1993), in which Gapun villagers apply pre-existing theories of hidden meaning in language to their readings the Christian Bible, as they seek passages which will unlock the secrets of Cargo wealth. Such an encounter is also the object of Pulis' (1999) study of Rastafarian citing-up, a reading practice which emphasizes playing with the **sound** of scripture in order to tap meanings hidden by the literal or denotational meanings of the text. In some cases, the holy language can be used for other supernatural purposes, which are organized in accordance with local practices. In Bledsoe and Robey's discussion of Mende, ritual specialists substitute "Muslim magic" for indigenous magic and sorcery: "A *moriman* uses his command over Arabic writing, which is widely regarded as the literal word of God, to obtain God's assistance. He evokes a verse's power by writing it on paper, rolled into a tight wad and tied with string or inserted in a small amulet pouch (Bledsoe and Robey, 1993: 118)." Note in this case the condensation of talismanic power and artifactualized language: the verse, written in "the literal word[s] of God," is compacted into a tight wad and inserted into an amulet pouch.

A theme explicitly discussed in Wogan's work on magical writing is that occult uses of literacy are often in counterpoint to the official organization of literate practices in the service of state functions. For the Ecuadorian state, the practice of registering people and land is part and parcel of being a modern society. Salasacan magic writing is, of course, viewed as a premodern superstition, albeit one that shares a belief in the life-defining efficacy of writing in books. The general point here – that literacy practices are intertwined conceptions of modernity – has been widely discussed. An early and highly controversial claim by Goody was that (Western) literate traditions were causal forces in the creation of modern, democratic forms of government; this was echoed in Olson's early general statements about literacy and modern science. Their claims were effectively criticized, but as an ideological assumption, as separate from what we might call historical understanding, the equation of literacy with modernity in the West is widespread and pervasive (see Street, 1984; Collins and Blot, 2003: Chaps. 2 and 4, for critical discussions).

The pertinent question, of course, is what is meant by 'literacy' or 'modernity.' Some recent linguistic anthropological work provides a nuanced approach to the issues. In *Voices of modernity: language ideologies and the politics of inequality*, Bauman and Briggs (2003) discuss the way in which major philosophical works, developing a conception of modern versus traditional society, depended on a highly selective viewing of language. A case in point is provided by John Locke's essays on the foundations of knowledge and forms of government. In both kinds of essay, Locke treats language as a purely literal-referential communicative device, stripped of its interactional or contextual dimensions. (His view of language is thus like overly generalized conceptions of literacy, common enough in the 20th century, which equate an

undifferentiated literacy with a singular modernity.) As Bauman and Briggs show, there are many intellectual traditions, ranging from Classical Empiricism through Antiquarianism, Folklore, and Boasian Anthropology, which have differently stipulated what is essential to 'language,' while giving priority to specific **entextualizations** of language, as part of their projects of establishing boundaries between the modern and the pre-modern.

Reporting from a very different part of the world, and treating a more modest historical scope, Schieffelin (2000) also grapples with the issue of literacy and modernity. In her article she analyzes how the Kaluli of highlands Papua New Guinea have responded to Christian missionary activity and the variety of literacy practices attendant upon such activity. Analyzing missionary grammars (structural linguistic descriptions) and literacy primers, she shows how descriptive and prescriptive documents systematically skew the form of Kaluli language like importing Anglophone notions of literacy and encouraging reading and writing activities of a church-appropriate type. Kaluli literates, for their part, bring a local slant to interaction and interpretation. They read in groups, rather than in isolation, and they interpret written language as speech, in accordance with Kaluli beliefs about what is primary: talk rather than text. These local appropriations notwithstanding, Kaluli of the 1980s, after some 50 years of missionary activity, have adopted a modern ideology of authoritative truth: it resides **in the written text**. The blending of imported categories of description and practice with indigenous ones is part of a local modernity that Schieffelin deftly characterizes. But the Kaluli are nonetheless drawn into what she calls "colonial and missionary intrusions . . . premised on the principle of asymmetry: domination, control, and conversion . . ." (Schieffelin, 2000: 321).

One general lesson from this work is that in thinking about literacy ideologies and long-term developments, such as the emergence of modernity, it is wise to seek out variation in and dialogic exchanges between the so-called modern and non-modern. It is also important to be aware of the frequent connection between literacy practices and forms of power and authority, to which we now give our attention.

Institutions, Language, and Social Structure

Investigating ideologies of literacy and of language more generally can help in understanding literacy practices as doubly-articulated phenomena, that is, as enacted in events while also informed by ideological overlays. Efforts to understand the relation between empirical events and abstract entities such as models must, however, also attend to literacy institutions and their authority with respect to language, language use, and social differentiation. Religion and education are two well-known examples of such institutions.

As Goody (1986) and numerous others have noted, the spread of ancient civilizations, with their city states, extensive taxation, and conscript armies, typically also featured priestly castes and temple complexes, which were distinguished by their knowledge and control of an esoteric literacy dividing elites from masses. World religions are also famously "religions of the Book" and struggles to control the book – its script, language, or interpretation – are struggles through which knowledge becomes power and power knowledge.

Even in relatively modern times, the elite concern to regulate mass forms of literacy is evident. One of the first known national literacy campaigns, in 17th century Sweden, also featured national literacy tests. A country with high literacy rates and surprising gender equality in those rates, Sweden's literacy campaign featured household instruction and religious oversight: parish supervision and compulsory testing to ensure not just reading but orthodox, Protestant reading (Gee, 1996: 32–34). Besnier's close analysis of Nukulaelae church services brings out the way in which religious **institutions are enacted**, how categories of person, and knowledge, and text are combined in communicative events: e.g., the sermon. In such events, differences between the kinds of person are presumed, displayed, and thus reproduced: for example, between the Christian and un-Christian; and between men who write and women who read. A limiting case of sorts is suggested by dissenting, hybrid religious movements. The examples of Silas John and Oshitelu show that a prophet, his writing, and chosen readers, can mobilize charismatic authority, in claiming and performing divine access through scriptal practices, without substantive institutionalization of offices, personnel, or resources. An important point revealed in all these cases, as in those discussed by Schieffelin (2000) and Wogan (2004), is that something significant occurs with the locating of authority, truth and correctness **in text**. Epistemologies and ontologies shift as well as what we might call social technologies of language. Artifactualized language is subject to different dynamics of accumulation and distribution than non-artifactualized language, with different potentials for ideological articulation and institutional consolidation.

Ever since Socrates's voice was transmuted into Plato's writings, the school as well has been a paradigmatic literacy institution. Since the time of the Greek and Roman empires, the *scola* has been the primary site for drawing boundaries between the idealized uniformity and consistency of civilized

language and the hybridizing variety of barbarian tongues. It is a familiar story that nationalism feeds upon and promulgates the standardizing of language, a political impulse toward centralization and control given great efficacy by the institutions and agents of the nation-state and the colonial regime, accompanied, to be sure, by local interpretations and reworkings (see Gee, 1996; and Street, 1984 and 1993, for discussion of general mechanisms and cases from national, colonial, and postcolonial settings). There is considerable historical and ethnographic work showing that schooled literacy is a particular institutional regulation of appropriate practices of reading and writing in correct forms of language, a mode of contemporary power which is also inextricably connected to dynamics of subjectivity and identity formation (see Collins and Blot, 2003, Chaps. 4 and 5, for discussion and extensive bibliography).

That schooled literacy in the United States, for example, reflects and helps reproduce patterns of race and class inequality is both a familiar claim and the proverbial tough nut to crack. The undeniable persistence of racialized class inequality in literacy attainment has fueled an ongoing sense of a literacy crisis in late 20th and early 21st century America, yet neither side in the acrimonious reading wars of the last decade have much compelling evidence that their pedagogical proposals to improve school literacy achievement will do that, let alone lessen general economic inequalities. The current plight is well characterized in Rogers' (2003) ethnographic and critical discursive analysis of the panacea of family literacy, which focuses on one African-American family's multigenerational struggles with schools, Special Education referrals, and the damaged identities that result from literacy failure. Rogers, an ardent believer in the value of literacy and education, nonetheless writes:

> . . . research in New Literacy Studies has demonstrated that parents of working-class and minority children do value education and school and are involved with their children's education. I want to suggest that **it is precisely because of this belief and involvement that working-class and minority families' efforts are thwarted within the institution** (Rogers, 2003: 144, emphasis added).

One way of thinking about valuing education and encountering failure in school and the workplace, a way of moving beyond the current political opportunism of reading reform, is suggested by Brandt's (2001) historical analysis of literacy traditions and practices in 20th-century America. Drawing on Bourdieu's writings about social fields and her own historical material, Brandt argues for the concept of bold sponsors of literacy, providing more dynamic accounts of social institutions – of family, church, school, and the workplace – and their intertwined role in promoting and regulating literacy practices.

Taking Stock: New Literacy Studies, Linguistic Anthropology and Indexical Analysis

In the preceding I have discussed the New Literacy Studies' formulation of literacy practices and some of the empirical work developing this conception. Interwoven with and as complement to that discussion, I have drawn on research on the history and anthropology of literacy, seeing this especially as part of a general sociocultural perspective on literacy practices. I have emphasized the artifactualization of language, uses of artifactualized language, especially in the domain of religion and the occult, the ideological articulations of such uses, and the significance of literacy institutions and their authority in order to discuss analytic and substantive issues relevant for understanding literacy practices understood as sociocultural phenomena. These are issues which are mentioned in various NLS works; indeed it is a truism of NLS work that literacy is ideological, but on my reading these issues are not given sufficient theoretical attention or empirical priority **in their inter-relation**.

One way of approaching this argument is to note, again, that most work on literacy practices posits a two-way relation: between events and models. Within linguistic anthropology, the subfield of anthropology that takes language analysis as central to a more general project of sociocultural inquiry, much work on language function and ideology has either been explicitly cast as practice (e.g., Hanks, 1996) or has developed via theory and analysis of indexicals (e.g., Ochs, 1996; Silverstein, 1985). On my reading, this work shares a fundamental assumption: that overcoming the dichotomy of the linguistic/social requires analysis of a three-way relation: between language **form** (system), language **use** (acts, events), and language **evaluation** (an ideological or reflexive aspect of social process and communicative conduct).

There is now a small but growing body of work which uses analysis of indexicality to investigate the sociocultural processes in which literacy practices are situated and to which they contribute. I have discussed this briefly above, with regard to Bialostok's work on models of reading and Shuman's discussion of talk–text interactions among working-class adolescents. Two general points may be made regarding this work and indexicality more generally. First, analysis of indexicals entails a commitment to systematic investigation of language–context relations, with healthy concern for interpretive complexities. Second, it requires as well an awareness that many

language–context indexical relations are indirectly related to – they **indirectly index** – other sociocultural constructs and processes, which are themselves essential to the larger analysis. Briefly put, I think that indexical analysis offers a promising entrée to the interplay between microanalytic language use (events) and macroanalytic sociocultural constructs (including models). Let me turn to some examples. Silverstein (1996) is an influential discussion of the indexical underpinnings of language standardization in the contemporary USA, linking such standardization to general semiotic-economic processes, such as commodification, and ideologizing strategies, such as naturalization. More recent explorations of indexical dimensions of literacy and learning include attention to long-term interactional development of student identities; the indexing of unspoken models of appropriate literacy; the interplay of heterogeneous voices, pedagogical innovation, and globalized discourses of learning; and the assembly of knowledge and identity in dispersed, digitally mediated work settings (see studies in Wortham and Rymes, 2002). Blommaert (2005) provides a series of illustrative cases and analyses of literacy practices within orders of indexicality – authoritative frames for reading and writing events – which organize postcolonial and diasporic encounters between Africans and Europeans. Collins and Slembrouck (2004) develop a related line of inquiry via a case study of the reading practices encountered in situations of dense, migration-based multilingualism.

Conclusion

I have concluded with a brief discussion of work using indexical analysis to investigate literacy practices because it shares with research in the NLS framework a concern to grasp the simultaneous, ongoing interplay between the microphenomena of everyday life and the macrophenomena of institutional orders, unequal resources, and accumulated power and authority. But the work on indexicality holds more closely to what I take to be an important insight from linguistic anthropology: that understanding communicative practices, in our case, literacy practices seen as total social facts, requires attention to language form, use, and evaluation. Such a three-way analytic can lead from situated communicative doings to longer-term structuring processes, while remaining attentive to cultural dynamics. I think the foregoing discussion of religion, magic and literacy practices illustrates some of the issues involved.

It must be borne in mind, however, that concern with literacy practices is not just an effort to better understand literacy, though it is that. The concept emerged along with the New Literacy Studies, which were themselves an effort to consolidate a critique against earlier models of literacy, in the academy and officialdom more generally, which privileged Western literate traditions and minds over other traditions and minds. In their concern to uncover and demonstrate the logics underlying mundane practices by the economically, politically, and culturally disfavored, NLS practitioners share with anthropologists a number of philosophical, analytical, and substantive concerns, and they share also, I would suggest, an ethical commitment to anthropology as cultural critique. In the urgency of their normative stance, they may focus overly much on legacy of the school in shaping literacy practices (an indictment in which I would place myself in earlier textual manifestations), and in widening this focus, sociocultural perspectives are invaluable. But in their normative stance, NLS practitioners also remind academic anthropology that knowledge matters – in struggles as well as deliberations. Let this article be a contribution to and encouragement of continuing exchanges, on the common ground of literacy practices, between critical anthropology and new literacy studies.

Literary Pragmatics

J L Mey, University of Southern Denmark, Odense, Denmark

© 2006 Elsevier Ltd. All rights reserved.

The efforts to relate the study of literary texts to the science of language have mainly taken two directions. In an earlier, quantitative approach, the emphasis was on how to characterize a text, based on the occurrence of certain elements (substantives, adjectives, and so on). The methods employed were mainly statistic. Later approaches focused on the qualitative aspect: how to account for certain characteristics (grammatical constructions, literary tropes, etc.) thought to be specific for types of text or, more generally, how to characterize a stretch of text in relation to what used to be called 'extralinguistic' purposes: persuading, arguing, questioning, etc. – matters that used to be taken care of in the discipline called rhetoric (*see* **Rhetoric, Classical**).

When talking about literary pragmatics, it is important to realize that pragmatics was not developed from inside linguistics but, rather, originated in related fields, such as philosophy, sociology, and the theory of interaction. The linguists were initially alerted to pragmatics through the aporias that arose within their strictly limited field of view (*see* **Pragmatics: Overview**). Similarly, literary studies did not 'discover' pragmatics by themselves; the approaches to the study of texts as related to the human users were developed simultaneously by philosophers, literary theoreticians, and pragmaticists. The purpose of these endeavors was to make sense of the fact that language does not always obey the strictures of the grammarians; indeed, the linguistic structure of a text has, in many cases, very little to do with the effects of a text, with what it 'does,' or with how a text is produced and consumed by the users.

Applying the definition of pragmatics as "the study of the use of language in human communication, as

The efforts to relate the study of literary texts to the science of language have mainly taken two directions. In an earlier, quantitative approach, the emphasis was on how to characterize a text, based on the occurrence of certain elements (substantives, adjectives, and so on). The methods employed were mainly statistic. Later approaches focused on the qualitative aspect: how to account for certain characteristics (grammatical constructions, literary tropes, etc.) thought to be specific for types of text or, more generally, how to characterize a stretch of text in relation to what used to be called 'extralinguistic' purposes: persuading, arguing, questioning, etc. – matters that used to be taken care of in the discipline called rhetoric (*see* **Rhetoric, Classical**).

When talking about literary pragmatics, it is important to realize that pragmatics was not developed from inside linguistics but, rather, originated in related fields, such as philosophy, sociology, and the theory of interaction. The linguists were initially alerted to pragmatics through the aporias that arose within their strictly limited field of view (*see* **Pragmatics: Overview**). Similarly, literary studies did not 'discover' pragmatics by themselves; the approaches to the study of texts as related to the human users were developed simultaneously by philosophers, literary theoreticians, and pragmaticists. The purpose of these endeavors was to make sense of the fact that language does not always obey the strictures of the grammarians; indeed, the linguistic structure of a text has, in many cases, very little to do with the effects of a text, with what it 'does,' or with how a text is produced and consumed by the users.

Applying the definition of pragmatics as "the study of the use of language in human communication, as

determined by the conditions of society" (Mey, 2001: 6) to the case of literary communication, we may say that literary pragmatics is concerned with the user's role in the societal production and consumption of texts.

The Linguistics of Texts

Early approaches to literary pragmatics (what used to be called 'text linguistics') took their point of departure in certain concepts that had been developed in linguistics mainly in order to cope with the needs of grammatical description. A text was thought of as a hierarchically structured complex of sentences, just as the sentence itself was considered a hierarchically structured unit of 'phrases' (noun phrases, verb phrases, etc.). A 'text grammar' was proposed in parallel to the sentential grammar developed by Chomsky and his school (see, e.g., van Dijk, 1972).

Later efforts were spurred on by the achievements of philosophers and pragmaticists such as Austin and Searle, who developed a theory of 'speech acts' – that is, utterances that did something in addition to being merely 'uttered': the 'illocutionary' vs. the simple 'locutionary' aspect (*see* **Speech Acts**).

The idea that utterances had a 'performative' and not just a 'constative' value (originally due to Austin, 1962) gave rise to a classification of speech acts into categories such as assertions, questions, orders, and apologies. Following on this, some suggested that we could look at a text as a gigantic 'macro-speech act' that had under it all sorts of individual acts, each expressed in some hierarchically ordered, linguistically recognizable form. This approach mostly failed, on several counts. First, it was not easy to explain what exactly the relationships were between the different acts making up the text. There was also the problem of the hierarchical constraints, which seemed unnatural, given the essentially linear, and often unpredictable, nature of textual 'speech acting.' However, the idea that sentences may be conjoined in deeper ways than just being strung together on the surface ('concatenated' in Chomskyan parlance) had taken hold. Similarly, the notion that language 'performed,' did something, led to the valuable discovery that certain sentences were 'doable' or 'speakable,' and others were not (Banfield, 1982).

Perhaps the most important insight into the nature of human language use as 'doing things with words' (Austin, 1962) was due, again, not to a linguist but to a philosopher, H. Paul Grice, who took the ideas developed by both Austin and Searle (1969) several steps further. In order to explain the regularity of human conversations and their mostly successful outcomes, Grice (1989: 26–31) postulated the principle of cooperation, stipulating that every person's contribution to a conversation should be commensurate to its purpose (including the aims and motives of the participants) (*see* **Cooperative Principle** and **Grice, Herbert Paul (1913–1988)**). Grice further suggested four conversational maxims regulating our cooperative handling of conversational information: making it sufficient (the maxim of 'quantity'), true ('quality'), relevant ('relation'), and orderly ('manner'). Any infringement of these maxims should be interpreted (assuming the general idea of conversation as cooperation) as implying an additional meaning: Breaking ('flouting') a maxim imparts a message that although not explicitly mentioned, nevertheless is understood. Grice's famous example is that of a professor writing a recommendation for a student, consisting of a statement as to the student's attendance in class and his correct English spelling – clearly irrelevant matters in the context – and thus implying that there must be a reason for the professor's unwillingness to cooperate, viz. that the student does not deserve a 'real' recommendation (Grice, 1989: 30) (*see* **Maxims and Flouting**).

Grice's notion of 'implicature,' as it is called, is of the utmost importance with regard to explaining how authors and readers go about 'cocreating' the literary work, as discussed later (*see* **Implicature**). It has often been remarked that the essence of art, visual or literary, is in the way we omit things, rather than saying them outright or representing them pictorially. When a queen utters that she is not amused, we understand perfectly well what she is, and we hide to escape her wrath. When God asks Cain, 'Where is Abel thy brother?' Cain realizes (since God of course knows exactly where Abel is and who killed him) that this implies the question, 'Why did you do this to your brother?' However, Cain refuses to cooperate in this conversation and tries to deny the implicature that he should have been 'his brother's keeper.' But in the next sentence, having 'answered' God's question with the pseudo-cooperative utterance 'I know not,' he shows that he indeed has gotten the implied message: 'Am I my brother's keeper?' (Gen. 4:9).

In the following sections, I briefly indicate the particular instances in which pragmatics meets with various linguistic and literary approaches, as they are dealt with in the remainder of this article.

The problems of text production and consumption are discussed first. Next, a brief discussion is provided of a concept that has gained increasing attention in the discussions during the past few decades: interactivity, understood as the active (specifically Gricean) collaboration between reader and author. Such a collaboration involves more than plain interaction, however: the relationship between the active partners is

'dialectic,' which means that neither the author nor the reader can claim exclusive possession of, or authority over, the text. Following this, I characterize this relationship as a 'cocreative' one: a text is not the exclusive work of the individual author but always presupposes the active collaboration of an audience, the readers. How this cocreation is orchestrated technically is the subject of the following sections, in which first some classical linguistic techniques of 'signposting' are discussed, and then the important pragmatic concept of 'voice' is introduced as that which brings the text to life. In particular, the 'point of view' embodied in the voice of a character helps us find our way through the textual maze; this 'vocalization' relies not only on signposting by means of linguistic devices but also on the techniques of cooperation and implicature (including flouting) that were mentioned previously. When the proper conditions for use of these techniques are not met, we may experience a phenomenon that I have termed 'voice clashing': voices speaking out of order, either by an author's fiat or (more often) by authorial negligence. The final section wraps up the discussion by stressing the human engagement that is the necessary condition for successful text work.

Production and Consumption

The following is a common model of production and consumption in our society: a producer delivers a product to the market, and the consumer pays the market price, acquires the product, and starts consuming it. After the transaction is concluded, producer and consumer part ways, never to meet again unless in special cases (foreseen by the laws regulating trade in our society), such as inferior product quality or unsatisfactory handling of the financial aspects of the purchase. This relationship is purely linear and unidirectional; the deal, once consummated, cannot be reversed (barring special cases such as return or repossession of the product).

One may be tempted to apply this simple model to the production and consumption of literary works: The author is the producer of some literary text, whereas the reader is a consumer who happens to be 'in the market' for a particular literary product. Once the book is bought, the reader is free to do whatever he or she wants to do with it: take it home and place it on the shelf in the living room, possibly read it, or maybe even throw it in the trash – or at somebody, literally or metaphorically.

In reality, things happen not quite like that. Buying a book is not like acquiring a piece of kitchenware or furniture. One does not just bring a book back from the bookstore: one takes home an author, inviting him or her into the privacy of one's quarters. The author, on the other hand, does not just make a living, producing reams of printed paper (granted, there are those that do), but has a message for the reader as a person. This is, eventually, why books are bought and sold: not because they are indispensable for our material existence, but because they represent a personal communication from an author to a potential readership – a communication that, in order to be successful, will have to follow certain rules.

Authors and Readers

The process of writing has been likened to a technique of seduction: a writer takes the readers by their hands, separates them from the drudgery of everyday life, and introduces them to a new world, of which the writer is the creator and main 'authority' (Mey, 1994: 162, 2000: 109). The readers will have to accept this seductive move and follow the author into the labyrinth of the latter's choice in order to participate properly in the literary exercise. The readers take the narrative relay out of the hands of the author: 'The author is dead, long live the reader,' to vary Barthes (1977).

Marie-Laure Ryan (2001) envisioned this reader participation along a twofold dimension: that of interactivity (in which the reader manipulates the text) and that of immersion (where the reader seamlessly identifies him- or herself with the text). In immersion mode, the reader is not just a spectator on the virtual scene: The 'role of the reader' is that of an "active participant in the process of creating the fictional space" (Mey, 1994: 155). As discussed later, the immersed reader is a 'voice' in the text; he or she is not only 'present at the creation' of the text but also to some extent its 'creator' (Barthes, 1977).

In literary texts in particular, the success of the story depends not only on the author but also to a high degree on the reader. In the process of creating the text, the reader is created anew, reborn in the text's image. This interactivity does not just happen on the level of the text: it involves a deeper layer, that of the self. What is created is not only the fictional space but also the reader in it, 'lector in fabula.' 'This book changed my life' is therefore not just a trite expression we employ to register an exceptional reading experience; such changes happen whenever we consume texts (including nonliterary genres, such as scientific and commercial prose, legal texts, etc., and 'texts' in a wider understanding of the term – theatrical and movie productions, the visual arts, and so on; Mey, 1994: 155). Updating our view on texts, we may even include here the virtual realities of the computerized world and its texts, as discussed by authors such as Gorayska and Mey (1996), Ryan (2001), and others.

Text Dialectics

A dialectic situation of interaction occurs when the interacting parties influence each other in such a way that the outcome of what one party does is determining for the other's ability to operate.

In language use, the pragmatics of interaction determines the game, whose very name is dialectics. When speaking or writing, we are always engaged in some communication (informing our partner about some event, apologizing for inflicted injuries or insults, promising services, telling a story, etc.). In this activity, we crucially depend on the other's presence and cooperation not only for the legitimacy of our speech acts but also for their very viability. Conversely, our interactors depend crucially on who we think they are and on whether they think of us as good partners in interaction. (After all, one can only tell a story properly to listeners whose interests one shares or imagines one does). The way we see ourselves and our partners, and how they see themselves and us, is essential to this dialectic process. The following section details how such representations come about and are managed.

Cocreativity

Pragmatically speaking, a text is the result of what Bakhtin (1994: 107) called "the meeting of two subjects." The life of the text "always develops *on the boundary between two consciousnesses, two subjects*" (Bakhtin, 1994: 106; italics in original) the two consciousnesses being the author's and the reader's. The author is by definition conscious of his or her role in creating the world of letters, the 'fictional space,' mentioned previously. However, the reader's consciousness is just as essential in cocreating this fictional universe. For Bakhtin, the reader is the (co-)creator of the text: It is in the dialogue between author and reader that the text, as a dialectic creation, emerges (*see* **Bakhtin, Mikhail Mikhailovich (1895–1975)**).

How do author and reader, these two 'consciousnesses,' navigate the fictional space? For a reader, it is not enough to identify with the author passively; the reader must consciously adopt the cocreator role, as it is assigned by the textual dialectics. Conversely, the author must consciously alert the reader to the signposts and other 'indexes' placed in the fictional space to enable the navigation process.

In some older novels, mainly those written in the 18th and 19th centuries, the author often appears on the scene in person, apostrophizing the reader and telling him or her what to do, what to feel, what not to object to, which 'disbeliefs to willfully suspend,' and so on. The 19th-century British writer Anthony Trollope was a master of this 'persuasion-cum-connivance,' as when he told the readership that he was unable to expatiate more on certain characters of his story: the publisher, a Mr Longman, would not allow him a fourth volume, so he had to finish the third and last of the Barchester novels at page 477 – and, well, since we are already at page 396 . . . ("Oh, that Mr Longman would allow me a fourth!" Trollope, 1857/1994: 306). The curious and eagerly co-creative reader hurries to the last page of the novel to find that its number is indeed '477,' just as the author had predicted. We cannot exclude the possibility that the reader may feel a bit taken in: the cocreative is morphing into the gullible.

Cases such as these are the exception, and readers will normally do no more than smile at discovering their complicity in what is commonly understood as an authorial prank. In other cases, the cocreativity that is needed to make the cocreative enterprise succeed, although less obvious, is (perhaps for that reason) considerably more effective. Notorious instances of successful 'reader deception' are found in the Argentine writer Julio Cortázar's work, as in the novella 'Historia con migalas' ('A story of spiders'; 1985). Here, the author consciously leads the reader down a 'garden path' of narration, along which the two female protagonists by default are assumed to be a male–female couple. Only in the story's very last sentence do they literally remove their morphological protection, along with their seductive veils (see Mey, 1992; the trick is pulled off successfully only in the Spanish original).

In the Cortázar story, reader seduction (involving the cocreation of a manipulated consciousness) is achieved without the reader's awareness – a typical requirement of certain literary genres, such as the joke or, as in this case, the garden path story. In other (more normal?) cases, readers are guided through the fictional labyrinth by certain indications as to where the narrative 'thread' is leading them, which readerly pitfalls they have to avoid, where to proceed with caution or alternatively with boldness, and so on.

Signposting

In the Cortázar story, the reader is led astray by the (mis)use of linguistic means. It is as if the author had changed or removed the usual road signs – a technique one could call 'deceptive signposting.' The question is what are these signposting techniques, and how are they normally used to bring coherence to a text when no garden paths or jokes are involved?

First, we have the time-honored concepts of 'deixis,' such as when articles and (personal) pronouns are employed to 'point to' a particular character. In particular, in anaphora, the relative pronoun is used to 'point back' (or, in cataphora, 'forward') to a

character or object that is already mentioned, or is going to be mentioned, in the story. The common concept covering these phenomena is called '(phoric) reference' (*see* **Deixis and Anaphora: Pragmatic Approaches**).

In addition, we have means to indicate the time and place relations that are of importance in order to establish and promote the flow of the story. Time adverbs such as 'today' and place adverbs such as 'abroad' tell us when, and where, the story is taking place. Also, we have sentence adverbs that give a particular flavor to a larger stretch of discourse, sometimes even an entire paragraph (e.g., 'regularly,' 'unfortunately,' and 'clearly,' especially when placed sentence-initially) (*see* **Parentheticals**).

As was the case in the Cortázar story, much of the correct understanding of a story is imparted through the use of gender-marked items, such as 'she' vs. 'he,' or by exploiting the difference between a male and a female form of, for example, an adjective. The latter technique is not always applicable in English; in the Cortázar case, the 'dénouement' comes when the unsuspecting reader finally is confronted with an unequivocal, female adjectival form: *desnudas* 'naked' (a Spanish fem. plur. since it refers to women; in the English translation, this point gets lost and the garden path leads nowhere).

In addition to these linguistic techniques, pragmatics offers the reader a great help. There is Gricean implicature, mentioned previously; furthermore, the author has at his or her disposal various ways of representing speech or thought, either by directly quoting a character's utterance (literally putting words in his or her mouth) or by indirectly reproducing what the character is thinking to him- or herself in 'free indirect discourse,' as in the following quote from Jane Austen (1810/1947: 191): "And now – what had she done or what had she omitted to do, to merit such a change?" Here, 'she' (Catherine, the novel's heroine) is musing about her sudden change in fate (owing to the fact that, unbeknownst to her, the father of her lover has discovered that she is no rich prospect after all); however, we are never told explicitly who this 'she' is: being competent, cocreative readers, we will know.

Characters are given 'voices' that we clearly and distinctly perceive as the characters' and theirs alone. This notion (including the phenomenon of vocalization) is discussed next.

The Voices of the Text

Vocalization

'Vocalization' is a powerful way of creating and maintaining the fictional space with the willing help and indispensable assistance from the readership, and of 'orchestrating' the dialectics of cocreativity between author and reader. Taken by itself, the term may be translated as 'giving a voice,' 'making vocal' (or 'heard,' depending on the perspective). In the context of literary pragmatics, vocalization means 'giving a voice to a character in the story' – in other words, making the character speak.

We are more or less familiar with the phenomenon from the simple fact of narrative dialogue. Whenever a conversation is included in the story, we hear the voices of the characters discussing current events or other matters of interest, such as how many kinds of love there are (compare Kitty and Anna's conversation in Tolstoy's *Anna Karenina*; 1889/1962: 155), or the advantages of married life as opposed to the single gentleman officer's existence, as enthusiastically described by General Serpuchovskoy to Vronsky – how he got his hands freed when marriage lifted the 'fardeau' of everyday worries onto his shoulders (Tolstoy, 1889/1962: 350). In situations such as these, the attribution of voices is done in a straightforward manner, more or less as it happens in a play: the lines are put into the mouths of the characters, given voice through the unique assignment of a familiar role name, and are often preceded by what is called a 'parenthetical,' such as 'he said,' 'she laughed,' and 'he cried' (*see* **Parentheticals**).

Voice and Focus

Vocalization is an intricate process, inasmuch as it not only gives voice to a character in the strict sense of speaking one's part, but also affords information about the character's perspective or point of view. What the voice indicates is not just the character as such (by naming the person) but also the viewpoint from which the character sees the other characters, and indeed the world. In this wider sense, voices range over the entire fictional space they create: "Utterances belong to their speakers (or writers) only in the least interesting, purely physiological sense; but as successful communication, they always belong to (at least) two people, the speaker and his or her listener" (Morson and Emerson, 1990: 129).

Vocalization always implies 'focalization,' a focusing on the characters' placement in the literary universe (Mey, 2000: 148). In Bal's (1985: 100) words, focalization is "the relation between the elements presented and the vision through which they are presented." This vision and these relations are not open to direct inspection by the reader's naked eye in as much as they are necessarily mediated through the voice of the author; consequently, they may have trouble being focalized properly.

The Pragmatics of Voice

In the absence of obvious signposts, such as names and parentheticals attached to the 'physiological utterance' (especially when we are dealing with an unspoken thought or an 'unspeakable sentence'), we may be unsure whose voice we are hearing. This is where pragmatics comes to the rescue.

In order to be speakable, a sentence, Banfield (1982) noted, must have a 'speaking subject" – not just a sentential subject, but one authoring the utterance that is placed in a context in which certain utterances are speakable by certain persons. Successful vocalization at the author end is matched by the reader's successful revocalizing: the reader cocreates the part of the fictional universe in which the utterance is spoken and attributes the voices univocally to the focalizing characters, including the speaking subject.

When Voices Clash

Voices may sound in harmony, or they may clash. A voice that is not in accordance with what we, as readers, know about the speaking character will jar, not sound right; we do not feel it is the voice of the character (but perhaps the voice of the intrusive narrator trying to disguise him- or herself as a character or even, as in the case of Trollope, as the author). Other clashes are often referred to as 'poetic license,' such as when animals are attributed vocalizations that are not in keeping with their animal status. In *Anna Karenina*, we encounter quoted thoughts ascribed to the bird-dog Laska, who is irritated at Levin and his brother because they keep chatting while the birds fly by, one after the other, without the hunters so much as bothering to point their guns at them: '"Look how they have time to make conversation – she thought – And the birds are coming . . . . In fact, here comes one. They're going to bungle it . . ." Laska thought' (Tolstoy 1889/1962: 185).

In other cases, the reader is confused, such as when voices speak 'out of order,' having access to material that is strictly not accessible to the characters, given their background, or even false (Mey, 2000: Chap. 6). Such 'clashes' may even be caused intentionally, for example, in order to obtain a comic effect by letting characters adopt modes of speech that are not commensurate with the speech proper to the events or characters (such as when a director purposefully introduces modern colloquialisms and slang into a Shakespearian play).

Conclusion: The Role of Pragmatics

The user has been the guideline in our reflections on the ways readers and authors participate in the common endeavor of creating a literary text. The dialogue we engage in as authors and readers is a dialogue of users; the 'dialectics of dialogue' has been invoked to explain the users' cocreative roles, as authors and readers, in establishing the textual object (e.g., a story).

However, dialogue does not happen in a vacuum; it is

> a dialogue of social forces perceived not only in their static coexistence, but also as a dialogue of different times, epochs and days, a dialogue that is forever dying, living, being born: Coexistence and becoming are fused into an indissoluble, concrete *multi-speeched* [italics added] unity. (Bakhtin, 1992: 365)

The voices of the text are anchored in the plurality of discourse, in a 'multispeeched' mode; this multivocality represents the dialectic relations between different societal forces (*see* **Discourse, Foucauldian Approach**). If it is true that texts only come into existence as human texts through an actual engagement by a human user (as already stated by Roman Ingarden in 1931), then a pragmatic view of text, particularly literary text, is anchored in this user engagement. Conversely, the user is engaged only insofar as he or she is able to follow, and recreate, the text supplied by the author. Among the voices of the text, the reader, too, has one; this vocalization is subject to the same societal conditions that surround the author. The textual dialogue thus presupposes a wider context than that provided by the actual text. As we have seen, pragmatics offers a view on this wider, social context and explains how it interacts with author, texts, and readers.

Literary Theory and Stylistics

K Green, Sheffield Hallam University, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Stylistics and literary theory would appear to coincide neatly in a concern for the language of the given object, literature. In one model, stylistics can be seen as a hyponym to the superordinate theory of literature, that aspect of theory that explicitly deals with locating and describing the particular language of literature. Yet stylistics is often marginalized as a literary-critical approach and has not enjoyed an easy relationship with many of the dominant trends in literary theory. Indeed, the term *stylistics* has suggested to some critics a rather marginal activity having to do with the niceties of an author's style; but it clearly is much more than that. In a broad historical context, stylistics has its roots in the *elocutio* of Aristotelian rhetorical studies. Crucially surviving from the rhetorical tradition, *elocutio* dealt with the appropriateness of the expression and the relevance of its stylistic choices. Thus, it is a focus on the language of the expression in a particular way to do with *how* the text means, rather than *what* it means. Here are the roots not only of stylistics, but also of formalist and structuralist analyses of the 20th century. Literary theory, in contrast, is a broad area of investigation covering linguistic, social, cultural, political, economic, hermeneutic, empirical, and psychological issues surrounding the production and consumption of literary texts.

Before the 20th century, the notion of style was a secondary product of the analysis of grammar and rhetoric. In the 20th century, it developed from *elocutio* to encompass almost anything to do with an explicit focus on the 'language' of the (normally literary) text; that is, its particular and manifest phonological, lexical, and grammatical features. Stylistics arose partly because of the need in literary criticism to work with a set of agreed-upon and defined terms for the analysis and description of a particular kind of language, the language of literature. Such a language would not be wholly derived from the study of rhetoric (though it would take from it where it felt it was necessary) but would be built upon modern linguistic analysis. Stylistics in the main has concentrated on literary texts (despite the offshoot and somewhat tautologous sounding 'literary stylistics'), although the concept of style extends beyond the literary. With its focus on the language of the text, largely (but not exclusively) treated in a synchronic manner, stylistics has obvious affinities with a certain kind of literary criticism, particularly what came to be known as 'practical' criticism. This critical approach, growing out of the work of I. A. Richards in the 1920s, focused on the mechanics of the text, its immanent language features, and gave the pedagogy of English literature an enormous boost by freeing it from the

Stylistics and literary theory would appear to coincide neatly in a concern for the language of the given object, literature. In one model, stylistics can be seen as a hyponym to the superordinate theory of literature, that aspect of theory that explicitly deals with locating and describing the particular language of literature. Yet stylistics is often marginalized as a literary-critical approach and has not enjoyed an easy relationship with many of the dominant trends in literary theory. Indeed, the term *stylistics* has suggested to some critics a rather marginal activity having to do with the niceties of an author's style; but it clearly is much more than that. In a broad historical context, stylistics has its roots in the *elocutio* of Aristotelian rhetorical studies. Crucially surviving from the rhetorical tradition, *elocutio* dealt with the appropriateness of the expression and the relevance of its stylistic choices. Thus, it is a focus on the language of the expression in a particular way to do with *how* the text means, rather than *what* it means. Here are the roots not only of stylistics, but also of formalist and structuralist analyses of the 20th century. Literary theory, in contrast, is a broad area of investigation covering linguistic, social, cultural, political, economic, hermeneutic, empirical, and psychological issues surrounding the production and consumption of literary texts.

Before the 20th century, the notion of style was a secondary product of the analysis of grammar and rhetoric. In the 20th century, it developed from *elocutio* to encompass almost anything to do with an explicit focus on the 'language' of the (normally literary) text; that is, its particular and manifest phonological, lexical, and grammatical features. Stylistics arose partly because of the need in literary criticism to work with a set of agreed-upon and defined terms for the analysis and description of a particular kind of language, the language of literature. Such a language would not be wholly derived from the study of rhetoric (though it would take from it where it felt it was necessary) but would be built upon modern linguistic analysis. Stylistics in the main has concentrated on literary texts (despite the offshoot and somewhat tautologous sounding 'literary stylistics'), although the concept of style extends beyond the literary. With its focus on the language of the text, largely (but not exclusively) treated in a synchronic manner, stylistics has obvious affinities with a certain kind of literary criticism, particularly what came to be known as 'practical' criticism. This critical approach, growing out of the work of I. A. Richards in the 1920s, focused on the mechanics of the text, its immanent language features, and gave the pedagogy of English literature an enormous boost by freeing it from the

contextual constraints of history and biography and treating the text on its own terms. It was thus an important precursor of Anglo-American New Criticism. The text's 'terms' were linguistic, both in detail and in use as metaphor. Stylistics is not to be confused with the New Criticism of the 1950s and 1960s, but it does share some methodological axioms, and the two approaches overlap in the 1960s.

Modern stylistic analysis really began with the work of Charles Bally (1909) and Leo Spitzer (1948) in the first half of the 20th century. Bally's *stylistique* saw literary texts as examples of particular language use, and his work prefigures later conceptions of register and mode (particularly in the work of M. A. K. Halliday and David Crystal). Bally was a pupil of Ferdinand de Saussure. Spitzer, however, saw 'style' as not so much a particular form of linguistic 'character' but as a manifestation of social or historical 'expression.' Spitzer's work is essentially the cultural interpretation of style, and he suggests another important line of stylistic investigation (be it literary or nonliterary). His work highlights an ongoing tension in stylistics between formal description of linguistic features and broader cultural, psychological, or historical or interpretative aspects of the text.

Put simply, the goal of stylistics is to describe the linguistic features of the object of analysis in such a way as to demonstrate their "functional significance for the interpretation of the text" (Wales, 2001: 438). Its relationship to literary theory is a complex one. In the 1960s, linguistics became the focus both of a certain movement in literary theory and of critical approaches that grew out of the close-reading methods of I. A. Richards and others. The way in which linguistics was used by literary theory and stylistics, however, was radically different. Stylistics in its anglicized form has tended to eschew the philosophical complexities and self-reflexive obsessions of literary theory and to use the practical methods of linguistics wherever it sees them as being relevant to a particular reading. Linguistic theory and practice is very much the handmaiden of stylistics, which eclectically draws on what are deemed appropriate terminology and discourse. The dominant linguistic theory throughout the 1960s and 1970s was undoubtedly that of Noam Chomksy and his followers, yet strikingly, stylistics almost ignored his work during this time. The Chomskyan influence is seen particularly acutely in the work of Ohmann (1964) and Levin (1962). Here, style is seen as a transformational option selected from a core form. Despite the central notion of 'transformations,' which could easily be related to notions of style (and is presented convincingly by Ohmann and Levin), Chomsky's work was seen as too abstract for the text-driven concerns of the stylistician.

Stylistics found a more sympathetic grammar in the work of M. A. K. Halliday, whose systemic grammar allowed stylisticians to link grammatical description with literary effect in a way that was more transparent than in the Chomskyan paradigm. Halliday's functional approach (Halliday called it *systemic-functional*) again uses the notion of language *choices,* but sees them determined by the uses or functions which they are seen to serve. Language is thus socially constituted and meaning cannot be formulated in isolation (in opposition to the formalist approach). Literary stylisticians approved of this view because it allowed the notion of literary 'style' to be part of a larger, sociolinguistic network. In the 1970s and 1980s, stylistics drew on a number of different methodologies and approaches, most notably the Hallidayan functional model, feminism, pragmatics, and discourse analysis, these approaches being dominant and extremely influential. Indeed the most obvious and striking development in stylistics in the last 20 years has been its recognition of the notion of 'discourse' – although this was not especially new and had a precursor in Crystal and Davy (1969). There are some parallels in literary theory in that following the radical movements of structuralism and deconstruction in the 1960s and 1970s, a more historicist approach began to be seen. This was not simply an opposition to the formalisms of, for instance, deconstructive methodologies, for the New Historicism often incorporated deconstructive practice (particularly in the work of Stephen Greenblatt). Rather, it was a widening of the linguistic context and a breaking down of barriers between literary and nonliterary writing.

Perhaps the most pervasive influence on stylistic analysis in recent years, then, has been that of discourse analysis, and there are again parallels with developments in literary theory. Discourse analysis can signal many things, from the most text-centered description of language fragments to broad, Foucaultdian speculations about power and language. Literary theory has drawn more on the work of Foucault than almost any other theorist of 'discourse,' and yet Anglo-American stylisticians remain suspicious of his writing and treat it with a degree of scepticism. What unites the Foucaultdian approach with those such as the Hallidayan, however, is a belief in the contextual nature of language and a focus on language 'beyond the sentence.' Further, there is a belief, not always made manifest, that the (discourse) stylistician should be looking at 'real' language; that is 'naturally occurring' discourse. Of course, literature provides us with a ready-made supply of 'real' discourse, although many discourse analysts reject this corpus, insisting that it is 'deviant' language.

However, the approach has been fruitful in the field of stylistics. Ronald Carter's influential collection of stylistics essays *Language and Literature* (1982) was followed by the volume *Language, Discourse and Literature: An Introductory Reader in Discourse Stylistics* (1989). The shift in focus is clearly registered in essay topics: the first volume is dominated by grammatical considerations, despite the inclusion of Deirdre Burton's influential 'Through glass darkly: through dark glasses' (a politico-stylistic analysis of Sylvia Plath's *The Bell Jar*). The latter volume draws heavily on developments in pragmatics and discourse analysis, including applications of Politeness Theory, Speech Act Theory, and Gricean pragmatics.

If we take discourse analysis in its broadest sense, then it is possible to also view stylistics, "as simply the variety of discourse analysis dealing with literary discourse" (Leech, 1983: 151). This may not lead anywhere, and rather sets stylistics adrift from other movements in linguistics. Stylisticians have tended to draw eclectically from developments in discourse analysis (as they had done from other developments in linguistics) and the related field of pragmatics. Speech Act Theory, Politeness Theory, and Critical Discourse Analysis are now the staples of stylistic approaches. Speech Act Theory has also been adopted by literary theorists with some success, though Derrida's interpretation is quite different from Searle's. Fairclough's Critical Discourse Analysis (1989) has been extremely influential in encouraging a more politically orientated approach to stylistics. Used primarily in the analysis of media texts, it has proven fruitful in some aspects of literary analysis, reflecting the challenge (or threat) posed by the spread of media and cultural studies over traditional 'English' courses. Critical Discourse Analysis in a literary context is exemplified in the work of David Birch (1989), Sara Mills (1997) and Michael Toolan (1996), among others. It has its roots in Hallidayan systemic-functional linguistics (although Hodge and Kress 1993, successfully employ a Chomskyan model for analysis) and is particularly concerned with the linguistic encoding of ideology in texts. Its main object is most naturally the language of the media, of institutions, and of government; but again, stylisticians are able to examine the ideologies evident in representations of these elements as well as taking the broader view of literature as an encoder of ideology. The integrationalist approach of Michael Toolan is influenced by the work of Roy Harris (1984 and *passim*) and rejects many of the fundamental tenets of Western linguistics while promoting a holistic view of language function. Fundamentally exciting and iconoclastic, its effect has yet to be fully registered in literary discourse analysis.

Literary theory in the second half of the 20th century was initially driven not by Chomsky or Halliday or Richards or F. R. Leavis, or even Spitzer or W. K. Wimsatt, but by the Swiss linguist Ferdinand de Saussure, whose *Cours de Linguistique Generale* (1917) exercised a profound influence on continental and Anglo-American literary criticism (and indeed criticism of other arts). Translations and reprints of the work increased dramatically through the 1950s, 1960s, and 1970s, as the *Cours* became the *sine qua non* of literary criticism. But the way in which Saussure was adopted by literary critics and cultural theorists was vastly different from the way that, say, Halliday, was adopted by the stylisticians. Saussure offered no grammatical method and only the broadest semantic theory, and so was not adopted 'practically' in the same way. What he offered literary critics and theorists was a way of conceiving meaning relations, and he did so by positing a number of crucial, and by now extremely familiar, ideas:

(i) The distinction between *la langue* and *la parole*
(ii) The essential arbitrariness of the linguistic *sign*
(iii) The arbitrary and conventional nature of the *sign*
(iv) The distinction between the *signifier* and the *signified*
(v) Language is binary and contrastive.

These five observations together revolutionized literary and cultural criticism and were thoroughly used and abused throughout the middle and latter part of the 20th century. Aberrant readings and deliberate misreadings of Saussure pushed literary theory into an extreme self-reflexive period in the 1970s. At first, Saussure's work was felt most keenly in literary structuralism, where content was bracketed off and structure became central. The literary text was seen to function like a sentence – a massive grammatical construction. Individual words (or signs) were mere fillers for essential structural functions and a sign's meaning was a result of its relation to other signs (in particular one in which it stood in binary relation to) and based on an arbitrary relation between the 'acoustic sound-image' (the signifier) and the concept associated with it (the signified). Thus, at a stroke issues of a text's 'meaning' were reduced to that of a text's structure. This fact coupled with misreadings of Saussure and extreme versions of the theory of the arbitrariness of the sign (*contra* Saussure), took criticism away from the delicate consideration of a text's aesthetic value and toward a consideration of literary practice as *sign*.

This is only one half of the story, however, for another version of structuralism took the notion

of binary and contrastive relations and utilized it to produce close and immensely detailed analyses of the meaning relations in individual texts (Riffaterre, 1966). Indeed, Riffaterre's work, particularly the essay on Baudelaire's *Les Chats*, became a model for a certain kind of structural-linguistic analysis. In this important work, many of the present-day issues and difficulties to do with the location and description of style are evident. Riffaterre draws on the Russian formalist school in his notion of literature as some form of stylistic defamiliarization, but he attacks the structuralism of Roman Jakobson and Claude Levi-Strauss for its undiscriminating location of features (which may or may not have stylistic significance). Riffaterre further is concerned with the effects of the language upon its audience.

In the early 1970s, debates about the relationship between linguistic analysis and 'traditional' literary criticism raged, particularly in the United Kingdom. The most famous of these was the Fowler-Bateson debate (1971) (see Simpson, 2004 for a reprint of this argument). Roger Fowler took it as axiomatic that language analysis was at the heart of literary criticism, while F. W. Bateson, a literary critic, suggested that literature possessed an 'ineradicable subjective core' which was simply not amenable to linguistic analysis. Essentially, this was a claim for the unique status of literary language and a swipe at so-called 'objective' methods of analysis. But for a decade in the mid-1970s to the mid-1980s, the linguistic critics held sway, and the two approaches to linguistic theory and practice outlined above came together in a peculiarly anglicized form. The work of Fowler drew on both the continental Saussurean tradition and the more pragmatic (not in the linguistic sense) and eclectic stylistic Anglo-American tradition. In works such as *Linguistics and the Novel* (Fowler, 1977) *and Linguistic Criticism* (Fowler, 1986), one will find the work of Halliday, Chomsky, and Saussure linked with the practical consideration and analysis of a range of largely canonical literary texts. Traditional areas of investigation were given a new look, with some new terminology. In Fowler's work, we find analyses of 'mind style,' of paradigmatic and syntagmatic relations, and of free indirect discourse – standard areas for later stylistic analysis. Fowler's work drew on structuralist methodologies, if somewhat eclectically, but typically avoided Barthesian excesses.

In theory, stylistics offers common ground for those perennially separate groups of literature and language specialists; but the two domains have developed from such different origins that the relationship is never clear. In 1960, Roman Jakobson famously stated that "a linguist deaf to the poetic function of language and a literary scholar indifferent to linguistic problems and unconversant with linguistic methods are equally flagrant anachronisms" (1960: 377). One could extend David Lodge's statement that "the novelist's medium is language: whatever he does, *qua* novelist, he does in and through language" (Lodge, 1966: ix) to literature as a whole. Literature is fundamentally language, and the linguist is interested in language. This language can be conceived of as fundamentally different from 'ordinary' language, or as different only to the extent that it contains a greater concentration of features already present in other forms of language. But whether the difference is seen as one of degree or one of kind, the object of analysis is still language. What could be simpler? Even with the arrival, or rather discovery, of Saussure by literary theorists, the relation between linguistics and literature was not made clearer. This is partly because linguists in the 20th century, following Humboldt and more recently Chomsky, tended to view language as an abstract system, whereas the principal domain of the literary critic was in the textual features of the text as artifact. Stylistics thus continues to see the text as the object of study, but instead of seeing it as part of a system, sees it more simply as a site where language is organized, and proceeds to utilize the methods of descriptive linguistics for a more focused and less subjective analysis of those textual features. For the stylistician, then, the text is both data (as a linguist) and artifact (as literary critic). This assumption of the literary artifact (and acceptance of it) has led to the stylistician's domain object being largely simply the literary canon. Literary stylistics does not engage much in debates about the canon (on the whole) – it accepts it as its object of study and analysis. This is because it is not a coherent theory of literature as such, but a collection of possible methodologies. As noted, stylistics often borrows from whatever methodology is prevalent in mainstream linguistics. Traffic the other way – stylistics influencing mainstream linguistics – is almost unheard of. The influence of Saussure brought literary criticism and linguistics both to treat the text synchronically (that is, without regard to time). Stylistics is still a predominantly synchronic approach which has found no parallel to the historicist developments in literary theory that have dominated since the late 1970s.

An important development in the broad field of linguistics in the late 20th and early 21st centuries is that of 'cognitive linguistics.' Cognitive Linguistics (as part of a broader 'cognitive science') is most notably associated with the work of Giles Fauconnier, George Lakoff, Ronald Langacker, Mark Turner, and Eve Sweetser, among others. Much is made of

the supposed *antiobjectivist* stance of the cognitivists, where language, thought, and conceptualization are seen to be *embodied*. Embodied experience is expressed through metaphors (hence the cognitivists' obsession with this trope), and knowledge is constituted through and by what are known as *conceptual metaphors*.

Cognitive stylistics naturally takes its lead from cognitive psychology and linguistics, having a number of key assumptions. The first is to do with the 'embodied mind,' an attempt to heal the Cartesian split between mind and body. Mental activity is 'embodied,' in that physical and cultural functioning is interwoven and finds outlets in our use of metaphors and other tropes. Humans are said to conceptualize abstract concepts in concrete terms, where modes of reasoning are grounded in our physical being. Metaphors such as 'success is up' are said to demonstrate this. However, it is too easy to take this as a given, or simple cognitive disposition. Eve Sweetser has shown that such movements from the concrete to the abstract develop over a period of time. The movement, for instance, from the following two meanings of 'see':

(i) I see the cat
(ii) I see what you mean.

shows a cognitive development in terms of historical semantic change. In its most enlightening form, particularly in the work of Sweetser, it can throw light on the development of semantic change and thus has a diachronic as well as synchronic aspect. There are some within the discipline who wish to replace the term 'stylistics' with the term 'cognitive poetics,' but, in my view, this is a dangerous move. The strength of the eclectic approach offered by stylistics is also its weakness: its restless search for new applications and new theories to galvanize the movement can also be seen as the capricious appropriation of others' work. The cognitive poetics 'revolution' shows the discipline of stylistics at its best and at its worst – sifting through the mass of theories and applications for the most appropriate for stylistic analysis and producing genuine interdisciplinary analyses or misappropriating theories and rushing too quickly to apply them to texts.

Catherine Emmott's (1997) work has made important contributions to our understanding of certain procedures of text-mapping, drawing on recent cognitive and discourse theories. Emmott avoids the pitfalls of what might be called the 'new' affective stylistics by resisting the temptation to speculate further upon the aesthetic considerations of the text. Cognitive poetics (sometimes given the term 'cognitive stylistics') has an uneasy relationship with literary theory, and indeed with traditional stylistics. We might, for instance, define 'literariness' in terms of "cognitive events triggered in the mind by linguistic stimuli" (Pilkington, 2000: 189). But how are we to locate and define those 'cognitive events' except by the description and analysis of the 'linguistic stimuli'? It is not clear how this is different from saying that the text produces a certain effect because of its relevant linguistic features. Traditional literary concerns reappear with a new metalanguage. The focus, as in other cognitive approaches, is, then, on how the text works (or how readers work the text) rather than what the texts means. The work of Stockwell (2002) and Semino and Culpeper (2002) outlines the major concerns of the 'new' stylistics and is usefully read alongside the more traditional stylistic work of Paul Simpson (2004). Jonathan Culler's (1975) notion of 'literary competence' is the main precursor here (in a literary-critical context), but there are also links to the earlier work of Stanley Fish (1970) and Wolfgang Iser (1978). The 'human mind' is the focus of critical attention; but the human mind is a troubling, elusive thing whose functions and very being have to be inferred from human actions and processes. The principal difficulty is that as the analyses of individual texts proceed, the focus on the workings of the 'human mind' is diminished. Typically, as readings become more engaged with the manifest features of the literary text, claims about the 'cognitive' aspect of the analysis are more difficult to sustain.

An alternative to the cognitivists' approach is presented in the work of David Miall (e.g., Miall and Kuiken, 1994 and passim) and others. Miall's work draws on the work of Samuel Taylor Coleridge and grows out of the theories of both Coleridge and the 20th century formalist Victor Shklovsky. Other influences include the Dutch discourse analyst Teun van Dijk. Miall's claim is that the literary text is a universe "whose laws are distinctive" (1994: 2), echoing a more traditional view of the literary artifact. Although he on occasions assumes a crude notion of what constitutes 'ordinary language,' he makes some important observations regarding the nature of the literary text. Most cognitive approaches describe a 'resource-limited' system in which cognitive structures economize comprehension by deleting irrelevant propositions, inferring relevant propositions and building macropropositions. But Miall suggests that literary texts reverse the economizing effects of schemata and other supposed cognitive features. Thus, Miall finds cognitive approaches inadequate and unable to account for the richness of literary language. At a stroke, he rejects a dominant approach and brings to the fore a traditional view of the literary artifact.

Closely allied to the burgeoning cognitive stylistics movement is the development of empirical stylistic analyses from the late 1980s. Empirical stylistics also draws on and is influenced by the growing field of corpus-based linguistic studies. It faces many of the same difficulties faced by the affective stylistics of Stanley Fish developed in the 1970s and the *receptionaesthetik* of Hans Robert Jauss of the same time. Do we account for general dispositions of an ideal reader, or do we try to account for the readings of individuals? In all cases, what is the role of stylistic analysis? In such cases, the common assumption is that nothing is 'there' in the text until a reader construes it – a seemingly trivial point which nevertheless has potentially devastating consequences for a discipline based on the close analysis of manifest linguistic features. Studies such as Steen's (1994) into readers' processing of metaphor rely on conventional interpretation of informants' responses and the sifting and evaluation of data. The corpus of literary texts is already there, as it were, as given.

After the tremendous developments and upheavals in literary theory from the 1960s to the beginning of the1980s, criticism settled to a period of prolonged historicism, whether politicized or not. The dominant strains have been in historicized analysis, postcolonial and feminist (and postfeminist) work, including psychoanalytical approaches. To be sure, criticism could not sustain its relentless self-questioning forever, and there has been a certain amount of retreat from critical neuroses and a reassessment of earlier critical and literary issues – even such hoary old-timers as authorial intention. Certainly, literary theory turned away from the kinds of linguistic concerns that had been fundamental to its development in the 1960s through to the 1980s and focused more on extending and challenging the canon and on forging closer relationships with historical methodologies. In some ways, language-study (in its broadest sense) has rarely been further from the domain of 'mainstream' literary criticism; and theoretical inputs and influences from mainstream linguistics (or out the mainstream) are rare.

In stylistics, many of its traditional concerns are still being explored, despite the proclamations of the cognitive stylisticians. In journals, one will still find work on free indirect discourse, on 'mind style,' on metaphor and metonymy, on speech acts and pragmatics, on feminist stylistics, and on transitivity. This is partly due to the fact that a certain kind of stylistics (particularly evident in British universities) is essentially a pedagogical tool, and many of these topics and approaches are still the core of stylistics and 'literary linguistics' courses both in Europe and in the United States.

Stylistics in Europe has tended to engage with the interface of linguistic and literary theory more readily than the dominant British model (which is largely conservative in its eclecticism). European work – especially from The Netherlands, Germany, and Spain – has embraced movements both in linguistics and literary theory to produce challenging and often exciting readings of texts. European stylistics has tended to incorporate issues in philosophy, both 'continental' and 'traditional,' in its approaches and analyses much more readily than its more conservative counterpart. Here we are likely to find Derrida, Wittgenstein, Russell, Said, Gadamer, Kripke, and Spivak rubbing shoulders with Halliday, Chomsky, and Leech and Leavis, Greenblatt and Harris. Stylistics and literary theory are closely related in this eclectic tradition. This is partly due to a tendency in Europe to embrace European philosophy more readily than in Great Britain and the United States and a desire to integrate the empirical and the philosophical. Thus, the 'great four' of critical theory (and related fields) who so dominated and influenced cultural analysis in the 1960s, 1970s, and 1980s – Jacques Derrida, Roland Barthes, Jacques Lacan, and Michel Foucault – were assimilated into European cultural theory readily. Coupled with a tradition of stylistic analysis (as in the work of Teun Van Dijk), this philosophical and cultural assimilation gave rise (and to a certain extent still does) fertile cross-disciplinary literary analysis.

Producing Definitions

Definitions of literature and of literary language are socially and historically variable. The history of both terms has been constituted by differently positioned readers and writers framing different answers to questions concerning an appropriate definition. In this respect, definitions of literature and of literary language should not be considered as 'ontological,' establishing an essential, timeless property of what literature or literary language is, but as 'functional' – establishing specific and variable circumstances within which texts are designated as literary, and the ends to which these texts are and can be used (cf. Fowler, 1997; Frow, 2002). It should also be remembered that the circumstances surrounding the production and reception of definitions – who makes a definition, at what time, in what place, and for whom – play a significant part in determining the currency of those definitions. As part of a linguistic encyclopedia, this article also produces definitions from within a particular context, one that tends to have institutional authority insofar as it is sanctioned by universities and school examining boards.

Literature and the Language of Literature

Producing Definitions

Definitions of literature and of literary language are socially and historically variable. The history of both terms has been constituted by differently positioned readers and writers framing different answers to questions concerning an appropriate definition. In this respect, definitions of literature and of literary language should not be considered as 'ontological,' establishing an essential, timeless property of what literature or literary language is, but as 'functional' – establishing specific and variable circumstances within which texts are designated as literary, and the ends to which these texts are and can be used (cf. Fowler, 1997; Frow, 2002). It should also be remembered that the circumstances surrounding the production and reception of definitions – who makes a definition, at what time, in what place, and for whom – play a significant part in determining the currency of those definitions. As part of a linguistic encyclopedia, this article also produces definitions from within a particular context, one that tends to have institutional authority insofar as it is sanctioned by universities and school examining boards.

Literature: A Brief History of Definitions

In one sense, the definitions of literature and literary appear straightforward; the phrase 'English literature' occurs everyday and is used often with apparent felicity. However, what kinds of texts are designated by the term 'literature' is the subject of ongoing debate. To understand what is at stake in these debates, it is useful to look at the history of the word. The following definitions are presented according to the order in which they appeared historically. However, this order should not be taken to suggest the wholesale replacement of one sense by another, as though the term 'literature' could be emptied out and replenished with meaning. Rather, many senses have remained and do remain in use, alongside other senses, complementing and conflicting with each other. The following summary derives from Williams (1983).

Literature came into English in the late 14th century in the sense of acquaintance with 'letters' or books. To 'have' literature was to be schooled in polite or human learning. For example, Henry Bradshaw, writing in 1513, spoke with contempt for "The comyn people" who "without lytterature and good informacyon Ben lyke to Brute beestes." Writing in 1605, Francis Bacon used the term to praise the learning of King James I: "There hath not beene . . . any King . . . so learned in all literature and erudition, diuine and humane." The state of being well read was here associated with the normal adjective from this period – literate. From Bacon's use of 'literature,' however, it seems that the condition of being well read was at times close to the objective noun – the books in which one was well read.

The evaluative overtones of 'literate' (and of its antonym, 'illiterate') persist to this day and are regularly implicated in definitions of literature. There remains a general agreement that reading literary texts plays an important part in literacy development and can be especially valuable in extending imaginative and intellectual development, aesthetic appreciation, and an understanding of how experiences of people in the past and present can be represented (cf. Showalter, 2002; Abbs, 2003).

The sense of literature as a kind of knowledge seems to have persisted until the late 19th century. However, the blending of senses suggested by Bacon – both knowledge of books and books themselves – indicates that a general change in meaning took place in the mid-18th century. At that time, literature emerged in a newly objective sense, designating the activity or profession of a man of letters, as well as the whole body of books and writing, the realm of letters. In his *Life of Cowley* (1779), Johnson referred to "an author whose pregnancy of imagination and elegance of language have deservedly set him high in the ranks of literature." Johnson's reference to "ranks of literature" pointed less to a hierarchy of types of writing than to levels of polite learning: "elegance of language." At the same time, 'literary' no longer remained simply synonymous with 'literate,' but extended its meaning to describe the practice and profession of writing; the concepts 'literary merit' and 'literary labor' emerged during this period.

As 'literature' came to designate a whole body of writing, so the sense of a corpus of works produced by a particular nation or in a particular period began to develop in the late 18th and early 19th centuries. The idea of a *Nationallitteratur* developed in Germany from the 1770s, whereas references to a national literature also emerged in collections of stories published during this period in France (*Les Siècles de literature française,* 1772) and Italy (*Storia della letteratura italiana*, 1772). The concept of English literature seems to have followed these European uses.

The identity and constitution of a national literature are fraught with sociocultural and political struggles. These struggles focus upon the concept of a canon, certain texts that are considered central to a tradition of literature within a culture. The existence of a canon leads to the institutionalization of texts. Certain texts are 'set' for study by examination boards, syllabus designers, and teachers teaching particular courses; in turn, these books are categorized by publishing houses as canonical or 'classic' texts, and the whole process even serves to define what is considered to be literature (cf. Hodge, 1990). There is a certain degree of truth, therefore, in the statement of Roland Barthes that "literature is what gets taught."

Indeed, the notion of a canon of great literary texts is most problematized when national curricula are being developed, and definitions of what constitutes a national heritage are inevitably foregrounded. For example, the dominance of the canon by male writers and by a version of English writing confined to native British writers has been questioned for its partiality and may in turn be connected with the powerful positions held by white Anglo-Saxon men in educational establishments, on examination boards, and in the control of national curricula. Such circularity cannot help but influence how interpretations of the constitution of a national literary heritage are shaped (cf. Eagleton, 1996; Docherty, 2002). It is also necessary to recognize that canons are not immutable. The recent admission to the canon of English literature of the writer John Clare and the corresponding relative relegation of such 18th-century writers as Gray and Collins indicate how tastes change and evaluations shift as part of a process of canon formation, with

which definitions of what literature is and what it is for are inextricably bound.

During the 19th century, the sense of a national literature developed alongside a second sense, which comprised a nexus of meanings – literature as art, as aesthetic object, and as the product of great imagination or creative genius. This nexus of meanings represents a narrowing of meaning from the earlier sense of literature – writing books and books themselves – toward specifically imaginative writing. Before this specialization of meaning, the domain of imaginative writing had principally been denoted by poetry. However, by the middle of the 17th century, this term 'poetry' was gradually confined to metrical composition. It is probable that this application of the term to verse, together with the increasing importance of prose forms such as the novel, made literature the most available general word. However, whereas poetry had designated skills of writing and speaking in the context of high imagination, literature, in its 19th-century sense, referred almost exclusively to writing.

The post-18th-century senses of 'literature' and such associated terms as 'literary' still have effective currency in academic and popular uses. Nevertheless, 'literature' is subject to constant change; it is not universally the same everywhere and is, as a category of text, eminently negotiable. Definitions of literary language are similarly protean.

Literary Language

Definitions of literary language necessarily entail theories of literature, regardless of whether these theories are explicitly announced or recognized as such. Two main camps can be identified, and these are grouped, rather loosely and at the risk of oversimplification, into what have variously been dubbed 'intrinsic,' 'formalist,' or 'inherency' models, on the one hand, and 'extrinsic,' 'functionalist,' or 'sociocultural' models, on the other (Carter, 1997, 2004). Inherency definitions are presented first not only because they are historically antecedent but also because their influence has been pervasive in the export of Russian formalism into American New Criticism and in its subsequent import into practical criticism in Britain.

Foregrounding and Defamiliarization

Formalist definitions, especially those of the Russian formalists, were predicated on a division between poetic and practical language. Russian formalists sought to isolate by rigorous scientific means the specifically literary forms and properties of texts. Because there is no exclusively literary content, they argued, poetics should concern itself with the *how,* rather than the *what*. Thus, early formalists, such as Shklovsky, Tynyanov, Eichenbaum, and Jakobson, gave special attention to the linguistic constituents of the literary medium – language – and drew on the new science of linguistics for their theoretical and descriptive apparatus. Their main theoretical position was that literary language is deviant language. It is a theory that has had considerable influence.

According to deviation theory, literariness inheres in the degrees to which language use departs or deviates from expected patterns of language and thus defamiliarizes the reader. Literary language use is therefore different because it makes strange, disturbs, and upsets a routinized 'normal' view of things and thus generates new or renewed perceptions. For example, the phrase 'a grief ago' would be poetic by virtue of its departure from semantic selection restrictions that state that only temporal nouns, such as 'week' or 'month,' can occur in such a sequence. As a result, however, grief comes to be perceived as a temporal process.

Deviation theory represents a definition of literary language that contains some interesting insights, but that on close inspection is theoretically underpowered. For example, consider the following four observations:

1. Norms are difficult to define, which in turn makes deviation difficult to measure. What is the norm? Do we not mean norms? Is the norm the standard language, the internally constituted norms created within a text, the norms of a genre, a particular writer's style, or the norms created by a school of writers within a period? If it is the norms of the standard language, then what level of language is involved? Grammar, phonology, discourse, or semantics? Because the greatest advances in 20th-century linguistics have been in grammar and phonology, formalist poetics has tended to discuss literariness, in a rather limited way, in terms of grammatical and phonological deviations.
2. What is defamiliarizing in 1912 may not be that in 1922, when readers have acquired a different set of expectations. Despite the formalists' claims for the ahistorical separateness of art and literature from other kinds of discourse, the concept of defamiliarization is predicated upon socially and historically specific reading conventions.
3. To equate deviation with literariness is to suggest that literary language cannot result from adherence to norms, which in certain literary periods was a prerequisite for the creation of patterns in literary language.
4. The distinction between literary and 'normal' or 'poetic' and 'ordinary' language can be

deconstructed by pointing out that deviation regularly occurs in such discourses as advertising, jokes, and newspaper headlines that are not institutionally connected with 'literature.'

However, the idea of literary language as language that can result in renewal or in new ways of seeing the familiar cannot be as easily discounted as some of the above observations might suggest. Still, deviation theory needs greater theoretical and linguistic precision for the definition to hold, and it needs to be considered and tested alongside complementary definitions.

Self-Referentiality

Another influential inherency definition is particularly associated with Roman Jakobson. Originally connected with the Russian formalists, Jakobson subsequently moved to the United States and in a famous paper (Jakobson, 1960) articulated a theory of poetic language that stressed the 'self-referentiality' of poetic language. In his account, literariness results when language draws attention to its own status as a sign and when consequently there is a focus on the message for its own sake. Jakobson's notion has been clearly explained by Easthope (1983):

> The poetic function gets into the syntagmatic axis something which would normally stay outside in the paradigmatic axis: It does so by operating a choice in favor of something that repeats what is already in the syntagmatic axis, thus reinforcing it.

Thus, in the examples, *I hate horrible Harry* or *I like Ike,* the verbs *hate* and *like* are selected in favor of 'loath' or 'support' because they establish a reinforcing phonoaesthetic patterning. The examples cited (the latter was Jakobson's own and is a slogan in favor of the former American President Dwight Eisenhower, whose nickname was Ike) demonstrate that poeticality can inhere in such everyday language as political advertising slogans.

Jakobson's definition is, like definitions of deviation theory, founded on an assumed distinction between 'poetic' and 'ordinary' language. According to Jakobson, in nonliterary discourse, the word is a mere vehicle for that to which it refers. In literary discourse, the word or phrase is brought into a much more active and reinforcing relationship, serving, as it were, to echo, mime, or somehow represent what is signified, as well as to refer to it. This emphasis on the representational nature of literary discourse is valuable. However, it should be pointed out that Jakobson's criteria work rather better for poetry than for prose and that he supplied no clear criteria for determining the 'clines' or degrees of poeticality or 'literariness' in his examples. Like other formalist analysts, Jakobson also placed too great a stress upon the production of effects, neglecting in the process the recognition and reception of such effects. The reader or receiver (or listener) of the message and his or her sociocultural position tended to get left out of the account.

Speech Act Theories

Accounts of literary language that attempt more boldly to underscore the role of the reader interacting in a sociocultural context with the sender of a verbal message are generally termed 'speech act theories of literature.' Speech acts are uses of language that, either directly or indirectly, commit the user or recipient to a particular 'action.' In applications of these theories to literary text study, one of the main proponents has been Richard Ohmann. Ohmann's basic proposition was that the kinds of conditions that normally attach to speech acts, such as insulting, questioning, and promising, do not obtain in a literary context. Instead we have quasi- or mimetic speech acts. As Ohmann (1971) put it:

> Since the quasispeech acts of literature are not carrying the world's business – describing, urging, contracting, etc. – the reader may well attend to them in a nonpragmatic way and thus allow them to realize their emotional potential.

The literary speech act is typically represented as a different kind of speech act. As Fish (1980) and Hillis-Miller (2001) have demonstrated, definitions of literary speech acts presuppose a distinction between two kinds of discourse: (1) 'nonliterary,' 'nonfictional,' or 'serious' discourse that in various ways hooks up with the real world, and (2) 'literary,' 'fictional,' or 'nonserious' discourse that operates with diminished responsibility to that world. The first discourse type is typically privileged and normalized by speech-act theorists and is presented as basic and prior, whereas the other is presented as derivative and dependent on 'normal' language use (cf. Fish, 1980). Hence, according to Ohmann's formulation, literary speech acts involve (on the part of the reader) a suspension of the normal pragmatic functions that words may have in order for the reader to regard them as somehow representing or displaying the actions they would normally perform. In this sense, a literary speech act brings a world into being for its readers or listeners, but beyond that does nothing.

Ohmann's theory, like inherency models, suffers from an essentialist opposition between literary and nonliterary language that is not really borne out by careful consideration. Pratt (1977), for example, has demonstrated that nonfictional, nonpragmatic,

mimetic, or disinterested playful speech acts routinely occur outside what is called literature. Hypothesizing, telling white lies, pretending, playing the devil's advocate, imagining, fantasizing, relating jokes or anecdotes, and even using illustrations to underscore a point in scholarly argument, are then, by Ohmann's definition, literary. Ohmann's theory also does not explain either the 'literary' status of certain travel writings or Orwell's essays on the Spanish Civil War (and Orwell would have been extremely perturbed if people read those essays as merely pretended speech acts). Neither does it explain why detective novels, science fiction, and popular romances that are fictional are not literary nor why the prose works of Milton or Donne, which are nonfictional, are literary.

There are limitations to the theory of speech acts. However, what work on speech-act theory has done is to pose the question of whether the literary speech act is different or whether all language can be used for literary purposes. It is a tradition that has led to the insertion of quotations marks around the word 'literary.'

Literature as Discourse

The definitions of literary language that have been considered so far tend to be intrinsic rather than extrinsic definitions; there has been a focus on 'the language itself,' rather than on the source of the definition or on the institutional or ideological context in which the definition is made.

In a sense, to describe literature as discourse is to open yet another can of wormy definitions – what is meant by 'discourse'? In a recent article, Steen (2004) explained that discourse analysis is a complex field of research in the social sciences that requires interdisciplinary and multidisciplinary cooperation among linguistics, psychology, sociology, anthropology, and poetics, to name a few. As a result, within "the linguistic view of discourse," Steen (2004: 161) explained, discourse analysts "can examine discourse as language with special attention to the encoding of a message, or as a reflection of, or stimulus for, individual cognition and action, or as a reflection of or contribution to social interaction, or as the expression of a symbol in a culture."

In an influential study of literature as discourse, Fowler (1981) analyzed literature as a particular form of social interaction. According to Fowler, a literary text is not simply a formal structure with such properties as grammaticality, cohesion, and rhetorical patterning such as parallelism, chiasmus, metaphor, and so on but is also the medium of a situated interaction with a source and a recipient:

> To treat literature as discourse is to see the text as mediating relationships between language-users: not only relationships of speech, but also of consciousness, ideology, role and class. The text ceases to be an object and becomes an action or process (Fowler, 1997: 77).

To examine literature as a social action or process, Fowler's analysis drew upon the functional analyses associated with such linguists as Michael Halliday. In this way, the linguistic structures of a literary text are explained according to the communicative purposes they serve: "Once we start looking at literature as a part of social process then texts are opened to the same kinds of causal and functional interpretations as are found in the sociology of language generally" (Fowler, 1997: 78). From this analysis, literature emerges as a sociolinguistic fact – a set of values and functions assented to (even if not consciously recognized as such) by members of a community: "The values are neither universal, though they are subject to a small range of types of historical explanation, nor stable, though they change slowly" (Fowler, 1997: 78).

Any attempt to define literature as discourse is liable to underplay both the role and the relative position of the reader *vis-à-vis* the text. However, recent research has revealed that strategies of engagement with a literary text may be described in two ways: as a cognitive and emotional process in the minds of readers, and as a socially and culturally mediated expertise with language (cf. Charlton *et al.*, 2004; Kuiken *et al.*, 2004). Reference made to discourse conventions in the following section is an attempt partly to reorient definitions of literature with respect to the operation of readers or, more specifically, reading communities that are located in particular social, political, and historical environments.

Discourse Conventions

Analyses of literature as discourse must acknowledge that the production and reception of texts take place in relation to socially negotiated conventions. Among students and critics of literature in contemporary Western culture, certain conventions form a basis of taken-for-granted 'common sense' about literature. In an educational context, for example, specific conventions underpin reading literature in what is an institutionally acceptable or 'competent' way (cf. Culler, 1975). However, it must be stressed that these competencies are 'conventional.' Whereas this article attempts to define literariness with respect to discourse conventions, it need not follow that literary discourse is always produced with such functions in mind. Furthermore, whether or not a reader *chooses* to read a text in accordance with these conventions, as a literary text as it were, is one crucial determinant

of its literariness. Gerard Steen (1994), for example, has demonstrated that by presenting a newspaper article first in its original context (as a newspaper article), and then in a 'perverse' context (as part of a novel), readers are inclined to note metaphors that are prototypically journalistic and metaphors that are distinctively literary, respectively.

The discourse conventions of a given interpretive community inform the definitions of literature that are current within that community. Stockwell (2001), for example, has noted that fiction emerges as the prototypical form of literature in much of modern literary theory. So central is the concept of the fictional that many studies of literary theory emphasize imagination and alternativity without recalling that much literature is religious, autobiographical, or political or describes real journeys, satirizes real people, or recounts real events.

The institutionally and discursively regulated forms of use to which texts are put are historically specific. However, as Tony Bennett (1990) noted, this is not the same as distinguishing between historically different forms of writing. Texts from any period can be retrospectively literarized by abstracting them from the different institutional and discursive forms regulating their initial use. In taking up these criteria, it must be emphasized that the production and reception of literary texts are historically specific, socially situated acts. Rather than designate particular linguistic features as intrinsically 'literary,' these criteria describe how features typically function as a part of contemporary literary discourse conventions.

The Literariness of Discourse

Literature may usefully be considered not only as discourse but also as a discourse that shares characteristics with other discourses. Put another way, the conventions for the production and reception of literary discourse may be considered with respect to a typology of discourses; the more a discourse conforms to these conventions, the more literary it is considered to be. Accordingly, Carter (1997) proposed a 'cline' of literariness, along which a typology of discourses may be situated as more or less 'literary.' He suggested the following criteria.

Medium Dependence

The notion of medium dependence means that, the more literary a text is, the less it will be dependent for its reading on another medium or media (see Carter, 1997 for a range of examples). This criterion is part of a tradition of attributing to literary texts the qualities of mimesis and fictionality. According to this tradition, literary texts generate a world of internal reference and rely only upon their own capacity to project. However, this is not to suggest that literary texts cannot be determined by external or social or biographical influences.

It should be borne in mind that the notion of medium independence is a particular preserve of critics and students of literature. An emphasis upon the relative medium independence of literary discourse should not detract from the ways in which readers mobilize literary texts for social and cultural purposes. Janice Radway (1989), for example, has examined criteria for 'serious fiction' that emerge among members of the Book-of-the-Month Club. Radway emphasized that, for what she called 'the General Reader,' the value of 'serious fiction' is "a function of its capacity to be used as a map which is, despite the status of its representation, a tool for enabling its reader to move about effectively in the world to which it refers." For the editors of the Book-of-the-Month Club, books in the category of 'serious fiction' function for Club members "in a way very similar to many self-help manuals, advice books, and reference volumes."

Displaced Interaction

What is conventionally regarded as a 'literary' text is likely to be one in which the context-bound interaction between author and reader is more deeply embedded or displaced. However, although a more literary discourse is likely to be characterized by medium independence and displaced interaction, literary texts continue to participate in a medium of interpersonal exchange. Whereas literary texts may not be dependent on any particular medium and interaction between author and reader is embedded or displaced, readers can and do mobilize the communicative function of texts for social and cultural goals. Robert Hodge (1990), for example, has examined how literary texts, marked by the mode of unreality, are able to express alternative or oppositional meanings that otherwise might be suppressed from the public arena.

Polysemy

A literary text conventionally will be read for polyvalent meanings and may be produced with such functions in mind (cf. Steen, 1994). One characteristic of the polysemic text is that its lexical items do not stop automatically at their first interpretation. Denotations are always potentially available for transformation into connotation; contents are never received for their own sake, but rather as a sign vehicle for something else. Polysemy is a regular feature of many discourse genres, including advertising. Several recent studies of the language of advertising, including Cook (2001), have identified such

characteristics as polysemy, which point to the literariness of this discourse genre.

Polysemy is a significant communicative function that is promoted and valued in particular contexts and that operates according to specific reading strategies. However, to claim that polyvalent meanings are promoted does not necessarily mean that any or all interpretations will be accorded equal value or will meet with equal acceptance within a given interpretive community. Moreover, in certain instances, promoting polyvalent meanings may carry a serious social significance.

Reregistration

The notion of reregistration means that no single word or stylistic feature will be barred from admission to a literary context. This is not to say that certain stylistic or lexical features are not regarded as more conventionally 'literary' than others. However, reregistration recognizes that the full, unrestricted resources of a language are open to exploitation for literary ends. As studies of novelistic discourse by the Russian theorist Mikhail Bakhtin (1984) suggested, not simply single words but also the characteristics of other discursive genres may be represented in a literary context. According to Bakhtin, the effects of reregistration, of appropriating the characteristics of another discourse as an object for representation, are often parodic or travestying. In certain instances, the parodic effects of reregistration have serious social consequences, as was illustrated in the case of the fatwa declared by members of Muslim communities against Salman Rushdie following the publication of his *Satanic verses*. In such instances, the parodic function of literary discourse may be interpreted as a threat to the monologic authority of hegemonic discourses (cf. Mufti, 1994).

Interaction of Levels: Semantic Density

A text that is perceived as resulting from the additive interaction of several superimposed codes and levels is recognized as more literary than a text in which there are fewer levels at work or in which they are present but do not interact as densely. A more literary text is typically perceived to exhibit a high degree of semantic density that results from an interactive patterning at the levels of syntax, lexis, phonology, and discourse.

Discourse Patterning

Criteria for literariness discussed so far have focused mostly on effects at the sentence level. At the suprasentential level of discourse, effects can be located that can help differentiate further degrees of literariness. Once more, these effects contribute to the semantic density of literary discourse, as patterns of clause and tense extend over a suprasentential level.

Literature and the Language of Literature: Some Conclusions

Literary language is not special or different, in that any formal feature termed 'literary' can be found in other discourses.

Yet, literary language *is* different from other language uses in that it functions differently. Some of the differences can be demarcated with reference to such criteria as medium dependence, reregistration, semantic density produced by the interaction of linguistic levels, displaced interaction, polysemy, and discourse patterning. What is prototypically literary will be a text that meets most of the above criteria. In contrast, a nonliterary text will meet none or few of these criteria; that is, it will be monosemic, medium dependent, project a direct interaction, contain no reregistration, and so on.

The worst excesses of paradox and the essentialist dichotomies of an absolute division into literary/nonliterary or fictional/nonfictional can be avoided by positing a cline of literariness along which discourses can be arranged.

The sociolinguistic and sociocultural context of the discourse is important. This article has attempted to indicate how certain of the functions of literary discourse may be mobilized by readers or even reading communities for social and cultural purposes.

Literature and literary language may best be seen as socially and historically variable terms, with differently positioned readers and writers framing different answers to questions concerning an appropriate definition.

Literature: Empirical Studies

J Hakemulder, Utrecht University, Utrecht, The Netherlands

Introduction

The empirical study of literature (ESL) concerns all aspects of literary communication. Using methods of the social sciences, researchers test hypotheses concerning the attitudes, and behavior of participants in processes ranging from the production of what are considered literary texts, their mediation, and their reception. One of the central aims of the field is to examine how literary communication differs from (or resembles) other forms of communication. It is an increasingly interdisciplinary domain, with literary scholars, sociologists, psycholinguists, cognitive and social psychologists, and anthropologists combining their insights and methodologies. In the past ESL has first seen scholars moving from traditional disciplines of the humanities (e.g., stylistics, narratology, literary theory) into cognitive psychology; conversely, psychologists became curious how results obtained in controlled experiments with artificial texts relate to responses to full-blown literary texts. Interdisciplinarity ideally enriches both sides of the equation, with, for instance, literary studies contributing refined taxonomies of narrative structures, and psycholinguistics contributing methodological rigor and available insights in narrative processing in joint efforts to establish characteristics of literary processing. In the early history of ESL we do not always see such fruitful interchange. Some of the work did not meet standards in either the humanities or the social sciences. However, a lot has changed.

The wide range of research traditions, as well as the many different cultural and language barriers may have hindered interdisciplinarity (Steen, 2003). However, cooperation is enhanced by the common

Introduction

The empirical study of literature (ESL) concerns all aspects of literary communication. Using methods of the social sciences, researchers test hypotheses concerning the attitudes, and behavior of participants in processes ranging from the production of what are considered literary texts, their mediation, and their reception. One of the central aims of the field is to examine how literary communication differs from (or resembles) other forms of communication. It is an increasingly interdisciplinary domain, with literary scholars, sociologists, psycholinguists, cognitive and social psychologists, and anthropologists combining their insights and methodologies. In the past ESL has first seen scholars moving from traditional disciplines of the humanities (e.g., stylistics, narratology, literary theory) into cognitive psychology; conversely, psychologists became curious how results obtained in controlled experiments with artificial texts relate to responses to full-blown literary texts. Interdisciplinarity ideally enriches both sides of the equation, with, for instance, literary studies contributing refined taxonomies of narrative structures, and psycholinguistics contributing methodological rigor and available insights in narrative processing in joint efforts to establish characteristics of literary processing. In the early history of ESL we do not always see such fruitful interchange. Some of the work did not meet standards in either the humanities or the social sciences. However, a lot has changed.

The wide range of research traditions, as well as the many different cultural and language barriers may have hindered interdisciplinarity (Steen, 2003). However, cooperation is enhanced by the common

ground that researchers share. The use of empirical methods, for one, stimulates the exchange of findings. Second, most researchers agree on the epistemological foundations of their work. One basic idea of ESL may be traced back to Mukařovský's (1974) distinction between 'artefact' (the signs on the paper) and the 'aesthetic object.' For an aesthetic object to be realized, someone must read the artefact, interpret it, and evaluate it. Consequently, to understand literature means to understand readers' responses. And this requires empirical methods of investigation. Another assumption shared by most researchers in ESL is that it is possible to discover regularities in what people do with literature. Many theories in literary studies generate hypotheses about such regularities. Researchers in ESL agree that these claims need to be tested empirically.

Origins

Besides the growing awareness among literary scholars of the inherently empirical nature of some of the problems in literary studies, there are a number of other developments that have led to ESL (Andringa, 1998). One is the rise of reception aesthetics in Germany. We can distinguish two basic ideas in this movement. Both are relevant to ESL. First, in Wolfgang Iser's hermeneutic approach, literary texts are interpreted from the perspective of the reader. It is important to note that 'the reader' here is a mere construct in the mind of the interpreter, and does not necessarily have anything to do with the empirical reader. A second idea in reception aesthetics concerns research in the history of literature, which, as Hans-Robert Jauss proposed, should focus more on readers' responses. Developments in literary history are best understood, he claimed, by investigating audiences' 'horizon of expectation' (their aesthetic and other norms) and the degree to which a given text meets (or does not meet) these expectations.

It is a small step from there to doing actual empirical research. This step was not taken by reception aesthetics, however. A call for moving from readers-as-construct to empirical readers was made by the German psychologist Groeben (1977), who pointed out that many of the concepts in literary studies could easily be operationalized. In addition, he argued, this would make literary studies much more relevant to society at large. Only a few years later, Schmidt (1982) provided a theoretical basis for ESL, describing the literary system in contrast to other systems in society. He pointed out the differences in terms of communication conventions: the 'aesthetic (or non-referential) convention' in contrast to the 'fact convention' used in other discourses; the 'polyvalence convention,' the unwritten agreement between authors and readers that the text may well have more than one interpretation, as opposed to the 'monovalence convention' used in other systems.

Another ESL strand comes from France, where mainly sociologically oriented researchers investigated the influence of extraliterary factors such as economy, politics, geography, and religion. Of central importance to the sociology of literature in France and elsewhere is the work of Bourdieu (1984). His concept of the literary field describes how literary evaluation is determined by sociological factors rather than properties of the aesthetic objects. All agents (artists, critics, art consumers) strive for symbolic value (social approval, status) to obtain, in the end, economic power. Lifestyle (which includes reading behavior) is conceived here as a mean for social groups to distinguish themselves from others and to ascertain group membership.

Yet another origin of ESL can be found in psycholinguistic studies, mostly conducted in North America. A number of researchers focused on the processing of narratives, some of them looking back at the work of Bartlett. Of importance to this field of research is schema theory, schemas being memory structures abstracted from idiosyncratic experiences. A large body of research concentrates on how readers build 'situation models,' that is, cognitive representations of the events, actions, characters, themes, and authorial intentions (van Dijk and Kintsch, 1983).

Another root of ESL can be found in America's reader response movement. As a result of democratization in education (and elsewhere in society), educationalists shifted their attention from a top-down approach of teaching how to arrive at correct interpretations of literary texts to an interest in what literature meant to students personally. Important in this movement is the work by Rosenblatt (1938), who focused on the influence of literary socialization on reading. Some of the research in this field is of a psychoanalytic nature and looks at how readers search for identity themes in the literary texts they read (Holland, 1975).

Mapping the Field

The origin of the research methods applied in ESL may lead us to distinguish two general directions: the psychology and the sociology of literature. However, such labels do not adequately represent recent developments in ESL, nor the research objects themselves. As to the latter, the various agents and processes in literary communication are affected by both psychological and sociological factors. Reception research focuses on readers' aesthetic evaluation, their reading

motivation, and the effect reading has on them. Although this field is dominated by psychological approaches, the processes involved are clearly also influenced by sociological factors (e.g., the institutional context in which readers read, and readers' literary socialization). In the sociology of literature researchers seek to explain differences in reading behaviors of social groups, and how institutions such as literary criticism are governed by social factors (e.g., a desire for status or social approval). However, exclusively relying on sociological models to explain, for example, aesthetic preferences ignores too much research showing the effect of text properties.

Hence the call of some researchers for an integrated approach, which does seem to be reflected in recent developments in ESL (Andringa, 1998). With overlapping interests, different methodologies and disciplines, and differences in the precise definition of the research object, the field has become too complex for a clear-cut distinction between the psychology and sociology of literature; therefore the present overview attempts an alternative categorization. First, research pertaining to production and distribution will be introduced. This work is mainly sociological, focusing, for instance, on economic conditions for literary production and on the influence publishers have on literary communication. Here we will also discuss studies exploring the market for literature: why do some people buy literary books, while others do not? In the next section, research pertaining to reception or processing will be presented, including a description of cognitive studies of narrative processing in general, as well as of research specifically pertaining to literary narratives and other literary genres. The final section on alternative categorization gives an impression of post-processing research – studies of reader behavior after reading the text. Here we find research pertaining to canonization, reception in literary criticism, and the effects of reading literature on readers' behavior, attitudes, norms, and values.

Production and Mediation

Strong evidence shows that socioeconomic factors influence developments in literature. Janssen (2001) reviews the research concerning the social-economic conditions for authors to do their work. Central to many of these studies is the term 'gatekeepers': agents in the literary field who are involved in selection (e.g., of which texts are actually published). Examples of research subjects are: the effect of censorship on the creative process; the effect mediators have on literary production, for instance, when looking at translations of Third World literature into modern Western languages; and factors influencing authors' careers. These are important efforts that could help to understand processes studied by literary historians (e.g., canonization). One example is presented in Peterson (1985). He shows how factors like copyright, technology, industry structure, and market affected the rise and decline of one particular genre, the short story in the United States.

Psychological studies of production processes seem somewhat underrepresented. Much work, it seems, still needs to be done to examine processes of literary creativity (Simonton, 1984). Research often involves self reports of writers. Other research compares creative and less creative persons to determine the factors that covary with creativity, both in personality (e.g., willingness to delay a decision, tolerance for uncertainty), and in biology. Under this subheading we could also place quantitative (rather than psychoanalytic) studies concerning the relation between, on the one hand, authors' personalities and events in their lives, and, on the other hand, the stylistic aspects of their texts (Janssen, 2001).

Distribution research concerns the factors that determine what books people buy or borrow from the library. Most studies focus on social-economic factors in reading behavior, the lion's share being inspired by Bourdieu's (1984) theoretical framework. In his view, aesthetic preferences have a social function. Like other lifestyle components, they are ways to affirm group membership. In understanding the dynamics of the literary field, researchers look at status: the more status agents have accumulated, the more their evaluation will be considered legitimate and the more influence they will have on canonization. Also, in striving to obtain status, agents deny their interest in economic capital. Only this will result in symbolic capital, which will, in turn, lead to economic capital. These ideas have had a strong impact on what is called the institutional approach in ESL, which looks at the role of publishers, literary criticism, and literary education on aspects of literary communication (Griswold, Jansen, and van Rees, 1999).

Recent studies present a more complex picture of reading audiences than Bourdieu's distinction theory predicts. Peterson's (1992) account of cultural stratification reveals there is no empirical evidence for a clear distinction between elite and nonelite culture consumption patterns. Instead, we see is an 'omnivore' audience that is involved in a wide range of cultural activities (including the elite arts), while a mainly low-educational 'univore' audience appreciates only a few nonelitist cultural activities. Other research shows that reading behavior can indeed be predicted by readers' social networks, but also by their cultural competence, personality, behavioral beliefs about the rewards of reading literature,

norms related to literary reading, and the promotion of reading by parents, schools, etc. (Griswold, Jansen, and van Rees, 1999).

Historical Readers An important subcategory of production and distribution research concerns the behavior of historical readers. These studies allow us to put current changes in reading audiences into perspective. Moreover, the history of reading may contribute to the contexualization of literary history. Literary history seems incomplete without knowledge of who the readers of the literary texts were, for whom the texts were written, what their expectations were, and how aesthetic norms changed through time and how such change affected reception. Research in this field is sometimes based on systematic content analysis of newspaper or magazine reviews. Some studies are based on sales records. One has to be careful interpreting these often incomplete data. Also, the data do not show whether the books were actually read. Taking these drawbacks into account, some interesting studies have been carried out about production and distribution in the past. For example, Kloek and Mijnhardt (1993) show that the so-called reading revolution in the 18th century is probably nothing more than a myth.

Reception

Under the heading of reception we will briefly review research on the processing of narratives in general and literary texts in particular, focusing on studies pertaining to processes that occur during and directly after reading.

An impressive body of cognitive research on discourse processing contributes to our understanding of how narratives are processed (e.g., Emmott, 1997). Of course, not all narratives belong to the group of texts referred to as literature, and not all literature is written in the form of narratives. Nevertheless, research results have been successfully applied in literary studies (for instance in cognitive stylistics, Semino and Culpeper, 2002). Central in many studies is schema theory, which proposes that schemata are essential to narrative comprehension processes and recall. These insights have proven to be useful in understanding, for instance, the role of genres in literary processing.

Other relevant examples of research issues are: the processing and accessibility in memory of information about characters; how readers keep track of speakers, of who said what, and who knows what; the causal inferences that readers make during reading; the conditions under which predictive inferences are made; inferences concerning the 'aboutness' or the theme of the text; the gender of the author; his or her intentions (e.g., Magliano, Baggett, and Graesser, 1996; Louwerse and van Peer, 2002). Cognitive psychology dominates this line of research. However, a growing number of studies investigates the role of affect (e.g., the effect of empathy on narrative comprehension; factors generating participatory responses (e.g., Gerrig, 1993).

Important for ESL is the relation of findings in narrative processing research to the processing of literary texts. Many of the studies mentioned above focus on factors that facilitate comprehension, causal sequence reconstruction, understanding character goals, etc. van den Broek, Rohleder, and Narváez (1996), for example, proposed a model for "successful reading of literary texts" that suggests that much depends on the construction of a coherent mental representation. This emphasis may lead researchers to ignore what is possibly typical for processing literature, namely those aspects that **obstruct** readers' understanding (*see* **Foregrounding**). Neither, of course, do the narrative models take response to poetry into account. Nevertheless, as Van den Broek *et al.*, suggested, the research does seem a useful starting point to examine **deviations** of literary narratives from more accommodating ones, thus discovering where literary processing differs from processing of other discourses.

One complaint concerning the studies referred to above is that they often look at seemingly insignificant 'miniature' hypotheses. Consequently, the results seem to be irrelevant to the bigger issues that would grant ESL more relevance within the humanities (Ibsch, 1996). Zwaan (1993) is arguably an exemplary study for ESL in the sense that he informs debates central to literary studies. His findings point out that readers process literary texts in a different way than other text genres. Thinking that they are presented with a literary text, readers read more slowly and remember more of the surface structure. This complies with what some literary theorists predict (e.g., Shklovsky, Jakobson).

Studies in narrative processing may not always seem of direct relevance to a better understanding of literary communication, but it should be noted that this is often not even the primary interest of the researchers, let alone that they claim to have solved the riddles of literary studies. Cognitive stylistics, however, explicitly aims at examining (literary) style and the effects it has on readers (e.g., Semino and Culpeper, 2002). While only a decade ago it may still have been feasible to summarize developments in this field, it is now not even possible to enumerate all the subjects of interest. Here we will therefore only look at a few examples. One is the field of metaphor research, especially those studies that pay attention

to the specific role of metaphors in literature (e.g., Steen, 1994; Hoorn, 1997). A second field pertains to the effect of foregrounding, a term used to describe where literary style deviates from daily language (e.g., see, for more empirical studies, **Foregrounding**). A third group of studies examines the effect of sound on reader response. Two approaches can be distinguished here: first, those studies that focus directly on readers' responses to sounds, either relative to context or not; second, studies based on computer-assisted content analysis (see, for a discussion, Miall, 2001).

A fourth group of studies, the lion's share of cognitive stylistics, can be labeled as psychonarratology, a term coined by Bortolussi and Dixon (2003). Methods of cognitive psychology are applied here to test empirical assumptions of narratology, the text-oriented study of narratives. Examples of research subjects are: the effect of narrative structure on feelings of surprise, suspense, and curiosity (Brewer and Lichtenstein, 1982; Vorderer, 1996); the effect of narrative perspective (Van Peer and Chatman, 2001); the processing of information about story characters; and how findings of social cognition research apply to perception of characters (Bortolussi and Dixon, 2003).

Differences in Reader Response A central question in reception research is (or rather, should be) 'How do differences in response to literature come about?' Are there general patterns or regularities in what moves readers, for instance, to feel sympathy for fictional characters? This is mainly the domain of psychology. Miall and Kuiken (1995) produced a Literary Response Questionnaire (LRQ) that was shown to be a useful instrument to differentiate between readers' attitudes toward literature. Studies under this subheading pertain to developmental differences, gender differences, and differences between expert and novice readers. In this last group, some studies reveal similarity in responses to textual features; others find that aesthetic norms and interpretation strategies depend on readers' literary competence. To make research findings in this domain more comparable, future research should more carefully describe 'reading experience' or 'literary competence' on the one hand, and text features on the other hand. Some research focuses on cross-cultural differences. Generally these studies show mixed results: some do find differences between readers from different cultures, but the majority point to similarities.

An important research tradition that may help understand differences in aesthetic evaluation can be found in experimental aesthetics (Berlyne, 1974). Berlyne's influential theory about the processing of aesthetic information conceptualizes art objects as psychological stimuli, some more complex, novel, or ambitious than others. The theory proposes that the more complex the stimulus, the more capacity is required from the perceiver (or reader) to process the stimulus. Exploring the relation between stimulus properties and aesthetic pleasure, the theory suggests an inversed U-curve (and in itself an instantiation of the Wundt-curve): appreciation will increase with increasing complexity, but only up to a certain point; after that optimum, appreciation will decline. Research in this field is often experimental. It sometimes involves physiological measures (of arousal), the interpretation of which is not always unambiguous. However, the results have been replicated under many different circumstances, using a wide variety of measures and stimuli.

Post-processing

Post-processing research mainly pertains to literary criticism, but also to the effects that reading literature has on the reader. The first category is dominated by the institutional approach. Some researchers look at the social dynamics in literary criticism to examine how consensus is reached over the value of literary texts. Findings suggest that that the relative status of critics affects their power over this evaluation process (Griswold, Jansen, and van Rees, 1999).

The second category mainly consists of psychological and educational studies. Researchers concentrated on the effects on norms, values, attitudes, and empathic ability (Hakemulder, 2000). Most of these studies do show effects, but few allow claims about the specific effects of literary communication. Some studies focus on literary education and its effect on literary socialization, on reading behavior at a later age, and on attitudinal effects of different educational approaches to literary education.

Current Trends and Debates

One of the important trends in the relatively short history of ESL is a shift from theoretical concerns (e.g., reflection on the epistemological foundations of the new discipline) to a predominantly research-driven approach, a development toward normal science in the Kuhnian sense (Steen, 2003). ESL has met with strong criticism from traditional hermeneutics, mainly focused on the superficiality of some of the research questions and the lack of external validity of laboratory experiments, but also fed by an indifference among scholars toward empirical validation and toward (naive) readers' interpretations of complex literary texts (e.g., Sternberg, 2003).

Some of these objections were also raised within ESL itself, and some important efforts have been made to remedy these problems. For example, more and more studies work with literary texts rather than experimenter generated ones, which has resulted in an increase in external validity. Careful manipulation of literary texts can sometimes compensate for the resulting loss of control. It may be advisable to conduct an evaluation of this method, after some time has passed, to see whether it is not systematically the manipulated version that has less effect (e.g., on aesthetic pleasure) than the originals.

One problem with much of the available research in ESL is that the population under investigation is rather limited (often undergraduate psychology students at some American university). However, some look at other age groups, and others take a cross-cultural perspective on response to literature. This will eventually result in greater generalizability of the findings.

ESL has seen a shift from radical standpoints (e.g., Schmidt's radical constructivism) to more integrated models (e.g., Bortolussi and Dixon, 2003). One single approach clearly cannot explain all the phenomena in literary communication, and therefore researchers need to take many factors into account to generate more comprehensive models. Accounting for institutions, or more generally the context in which people read, is essential when explaining literary evaluation. However, psychological research focusing on the effects of text properties leaves no room for one-sided absolutism.

Another development in ESL is a growing attention to the role of emotions in the reception of literary texts (Radway, 1984; Nell, 1988; Frijda and Schram, 1994). This seems to go hand in hand with the use of qualitative research methods. To assess spontaneous imagery and emotional responses, some researchers prefer free response, self report, and think aloud procedures rather than measures such as response time and closed questionnaires (e.g., Andringa, 2004).

A trend we can detect in ESL is that more and more researchers do not look at literary communication in isolation anymore, but put it in a wider context of media communication. Konijn and Hoorn (2005), for instance, have developed a model for perceiving and experiencing fictional characters for both readers and spectators of movies. This is also reflected in the work of such researchers as Vorderer (1996) and Schreier (Schreier, Knobloch, and Wieler, 1998).

ESL has seen boosts in its development every time researchers of different disciplines are brought together in joint projects, be it for conferences of the International Society for Empirical Studies of Literature and Media (Internationale Gesellschaft für Empirische Literaturwissenschaft, IGEL), or of the Poetics and Linguistics Association (PALA), book publications, or thematic issues of journals such as *Poetics* and *SPIEL*. Hopefully the future will see more of these fusions of literary studies and the social sciences.

The Republic of Lithuania is located on the eastern coast of the Baltic Sea. Lithuania borders Latvia, Belarus, Poland, and the Kaliningrad district of the Russian Federation. The country covers 65 300 km^2. Lithuania has a population of 3.48 million, of whom 66.9% reside in urban areas. According to the 2001 census, Lithuania consists of 115 ethnicities: Lithuanians make up 83.5%, Poles 6.7%, Russians 6.3%, and the others make up the remaining 3.5% of the population.

Lithuanian is the only state language used in all spheres of life. Its status as a state language is legitimized by the constitution of the Republic of Lithuania. Its public use is regulated by the Law on the State Language, adopted in 1995. Lithuanian is the mother tongue of the majority of the Lithuanian population. It is used as a second language by 356 000 non-Lithuanians, most of whom reside in the southeastern Lithuania and a few cities.

Lithuanian is one of the two Baltic languages of the Indo-European family (the other being Latvian). It is one of the oldest living Indo-European languages, and has retained many archaic linguistic features also characteristic of Latin and Sanskrit. The Lithuanian

The Republic of Lithuania is located on the eastern coast of the Baltic Sea. Lithuania borders Latvia, Belarus, Poland, and the Kaliningrad district of the Russian Federation. The country covers 65 300 km^2. Lithuania has a population of 3.48 million, of whom 66.9% reside in urban areas. According to the 2001 census, Lithuania consists of 115 ethnicities: Lithuanians make up 83.5%, Poles 6.7%, Russians 6.3%, and the others make up the remaining 3.5% of the population.

Lithuanian is the only state language used in all spheres of life. Its status as a state language is legitimized by the constitution of the Republic of Lithuania. Its public use is regulated by the Law on the State Language, adopted in 1995. Lithuanian is the mother tongue of the majority of the Lithuanian population. It is used as a second language by 356 000 non-Lithuanians, most of whom reside in the southeastern Lithuania and a few cities.

Lithuanian is one of the two Baltic languages of the Indo-European family (the other being Latvian). It is one of the oldest living Indo-European languages, and has retained many archaic linguistic features also characteristic of Latin and Sanskrit. The Lithuanian

alphabet has the Latin alphabet as its basis. It consists of 32 letters, some of which have certain diacritical marks to indicate special sounds. Lithuanian is an inflectional language. The noun has seven cases, and the verb has a particularly complex system of inflections. The stress is free.

Standard Lithuanian is about 100 years old, which makes it a relatively young language. It is used in all spheres of public life, education, and the media. In informal and semiformal contexts, regional and urban dialects are used. Two major dialects are distinguished: Aukštaičių (the Highlanders') and Žemaičių (the Lowlanders'). Standard Lithuanian was formed on the basis of the Western Highlanders' dialect.

Russian is widely known in Lithuania: 60% of the Lithuanian population use it as a second language. In Soviet times, before the restoration of independence in 1990, asymmetrical bilingualism was dominant: most Lithuanians could speak Russian, whereas most Russian speakers could not speak Lithuanian. Russian is the mother tongue of 89.2% of Russians. Many Belarusians, Ukrainians, Jews, Poles, and others also consider it as their mother tongue. At present, many Russian speakers are learning Lithuanian and becoming bilingual.

Polish is used as the mother tongue by 80% of Poles, most of whom reside in the capital, Vilnius, and its region. It is a local spoken variety different from standard Polish. A spoken variety of the Belarusian vernacular is used in rural southeastern Lithuania. Ukrainian, Tatar, Yiddish (Western Yiddish), Latvian, German (Standard German), and Romani are used as home languages.

Lithuania's major ethnic minorities have state-run schools with their ethnic language as the language of instruction and Lithuanian taught as a subject. Tertiary-level state education is offered in Lithuanian only. Ethnic minorities have TV and radio programs, newspapers, and magazines.

The most common foreign languages known by people in Lithuania are English (17%), Polish (9%), German (8%), and French (2%).

Lithuanian (*Lietùvių kalbà*) is the native language of some 2.9 million speakers in the Republic of Lithuania. Together with Latvian, it forms East Baltic, the sole remaining branch of the Baltic family of Indo-European languages. There are two major dialects of Lithuanian, the more conservative and territorially greater Aukštaitic (*aukštaičių tarmė*) and the more innovating Žemaitic (*žemaičių tarmė*; Samogitian), spoken in the northwest quarter of Lithuania. The standard language is based on the speech of the southwest Aukštaitic region, bordering former East Prussia.

The Written Language

The Writing Tradition in East Prussia

Lithuanian is attested in written form from the 16th century, in three varieties of the Aukštaitic dialect; the earlier texts are chiefly translated and original religious literature. Book publication in Lithuanian began earliest in German East Prussia (which had a substantial Lithuanian population) in connection with the spread of the Reformation. The first work published in Lithuanian is a 1547 translation of a Lutheran

alphabet has the Latin alphabet as its basis. It consists of 32 letters, some of which have certain diacritical marks to indicate special sounds. Lithuanian is an inflectional language. The noun has seven cases, and the verb has a particularly complex system of inflections. The stress is free.

Lithuanian (*Lietùvių kalbà*) is the native language of some 2.9 million speakers in the Republic of Lithuania. Together with Latvian, it forms East Baltic, the sole remaining branch of the Baltic family of Indo-European languages. There are two major dialects of Lithuanian, the more conservative and territorially greater Aukštaitic (*aukštaičių tarmė*) and the more innovating Žemaitic (*žemaičių tarmė*; Samogitian), spoken in the northwest quarter of Lithuania. The standard language is based on the speech of the southwest Aukštaitic region, bordering former East Prussia.

The Written Language

The Writing Tradition in East Prussia

Lithuanian is attested in written form from the 16th century, in three varieties of the Aukštaitic dialect; the earlier texts are chiefly translated and original religious literature. Book publication in Lithuanian began earliest in German East Prussia (which had a substantial Lithuanian population) in connection with the spread of the Reformation. The first work published in Lithuanian is a 1547 translation of a Lutheran

catechism by Martynas Mažvydas (Martinus Masvidius). The foreword begins with a personal appeal to the reader, *Bralei seseris imkiet mani ir skaitikiet* 'Brothers, sisters, take me and read me'. The language reflects Mažvydas's native south Žemaitic dialect, with Aukštaitic elements. Subsequent Lithuanian publications in East Prussia are written in an increasingly normalized variety of the local west Aukštaitic dialect, codified in Daniel Klein's 1653 *Grammatika Litvanica*, the first grammar of Lithuanian.

The Writing Tradition in the Grand Duchy

In the Catholic Grand Duchy of Lithuania, two writing traditions took root, one based on the East Aukštaitic dialect of the capital, Vilnius, and the other representing the Central Aukštaitic dialect of the Kedainiai area. The latter served as the medium for the earliest Lithuanian publications in the Grand Duchy, i.e., Mykalojus Daukša's 1595 translation of Jacobus Ledisma's popular Catholic catechism and his lengthy 1599 translation of Jakub Wujek's collection of sermons, the *Postilla Catholicka*. Although these were translations, the language of these works is relatively natural and had considerable influence on the later cultivation of Lithuanian. Daukša's works are also the first accented texts in Lithuanian, and as such are of particular importance for the study of the historical prosody of the language.

The National Standard Language

The increasing polonization of the Grand Duchy's nobility and educated classes led in the 18th century to a decline in the Central and East Aukštaitic writing traditions (the latter eventually disappeared). The present-day standard language has its roots in the late 19th century, and is based on the dialect of the southern West Aukštaitic region, in which the speakers are traditionally called *suvalkiečiai*. Several factors stand out in the establishment of this dialect as the national standard: the prior literary tradition of the virtually identical Aukštaitic dialect of neighboring East Prussia; the authority of the 19th-century Lithuanian grammars of A. Schleicher and F. Kurschat, which described the same Prussian Lithuanian speech; and the normative influence of late 19th- to early 20th-century newspapers such as *Aušra* (*The Dawn*) and *Varpas* (*The Bell*), which had many writers and editors (in particular Jonas Jablonskis) who came from the southwest Aukštaitic dialect area.

Phonology

Prosodic Features

Standard Lithuanian has free stress, which may alternate between a stem and ending within a grammatical paradigm, as in *dukrà* (nominative), *dùkrą* (accusative)'daughter'; *sakaũ* 'I say', and *sãko* 'he says'. There are four such stress patterns for nouns and two for verbs. Stressed long vowels and diphthongs (including sequences of vowel plus tautosyllabic resonant) distinguish two phonemic contour tones, traditionally referred to as acute (´) and circumflex (˜), as in *šáuk!* 'shoot.IMP' vs. *šaũk!* 'shout.IMP'. Short stressed vowels are marked with a grave accent (`). The tones are conventionally indicated in dictionaries and linguistic works; otherwise, they are not represented.

According to the norms of the standard language, acute tone *(tvirtaprãdė príegaidė)* is realized with a falling tonal contour, whereas circumflex tone *(tvirtagãlė príegaidė)* is level or rising. The tonal opposition is clearest on diphthongs; in the urban colloquial language, the distinction is becoming neutralized on long vowels. The phonetic realization of the two tones differs dialectally; in particular, the acute tone of northwest Žemaitic speech incorporates a glottal stop *(lauztìnė príegaidė* 'broken tone').

The Vowel System

Vowel length is distinctive in Lithuanian. The rather open short vowel phonemes /i [ɪ], u [ʊ], e [ɛ], a [a]/ (orthographically *i*, *u*, *e*, *a*) are inherited from proto-Baltic and also result from an early Lithuanian shortening of final long vowels under acute tone (compare *tà* 'this. NOM SG FIM' with Latvian *tã̃*, having the Latvian reflex of acute). In addition, a short /ɔ/ (spelled *o*) is found in words of foreign origin.

The long vowel phonemes /iː, uː, eː, oː, æː, ɑː/ (orthographically *y/i*, *ū/ų*, *ė*, *o*, *e*, *ą*) also have two sources. Inherited length is represented by the spellings *y*, *ū*, *ė*, *o [< *ā]*, as in *gývas* (**gī*-) 'alive', *bū́ti* (**bū*-) 'to be', *sė́ti* (**sē*-) 'to sow', and *brólis* (Latvian *brãlis*) 'brother', whereas *i*, *ų*, *e*, and *ą* develop from sequences of vowel plus tautosyllabic *n*, when not before a stop (where they are preserved). Original *V* + *n* sequences were first replaced by long nasalized vowels, marked in the earlier texts by a hook under the corresponding vowel graph. These vowels were eventually denasalized, although the orthography still reflects the earlier practice, as in *į̨* [iː] (< **in*) 'to, into', *siųsti* [ˈsʲũstʲɪ] (< **siuñt*-) 'to send', *tę̨sti* [ˈtʲæ̃ːstʲɪ] (< **teñs*-) 'to continue', and *žąsìs* [žɑːˈsʲɪs] (< **žañs*-) 'goose'. Both long and short *a* are fronted to /æː/ and /ɛ/, respectively, after a palatalized consonant or *j*, as in *gìlią* 'deep.ACC SG FEM' = *gìle* 'acorn.ACC SG FEM', both [ˈgʲɪlʲæ̃ː]; and *giliàs* 'deep.ACC PL FEM' = *gilès* 'acorns.ACC PL FEM', both [gʲɪˈlʲɛs].

Short *e* and *a* are automatically lengthened under stress in most nonfinal syllables to [æː] and [ɑː], with concomitant circumflex tone. This phonetic vowel length is not indicated orthographically, i.e., *ledas*

['læ̃ːdas] 'ice' and *vakaras* ['vãːkaras] 'evening' (compare Latvian *ledus* and *vakars,* having short *e* and *a*). Also included in the inventory of Lithuanian vowels are the diphthongs *ie* and *uo,* which arose from East Baltic **ę̄* (< **ei*) and **ǭ* (< **ō*). These diphthongs, which function as long vowels, begin with a high vowel and end with a lower, more central vowel (i͡ə, u͡ə), as in *dienà* (**dein-*) 'day' and dúona (**dōn-*) 'bread', phonetically [di͡ə'na] and ['du͡ə́na].

The Consonant System

Lithuanian alone among the Baltic languages preserves distinct reflexes (ʃ and ʒ) of the Indo-European palatovelars; in Latvian and Old Prussian as well as in Slavic, these have merged with *s* and *z*:, as in *šuõ* 'dog' and *žemė* 'earth' (Latvian *suns* and *zeme*). A characteristic feature of the Lithuanian consonant system is the phonemic opposition of palatalized and nonpalatalized consonants before back vowels (palatalization is automatic before front vowels). These palatalized consonants are the product of Baltic consonant + *i̯* sequences, which are still preserved in the case of labial stops in word-initial position, as in *pjáuti* ['pʲjǽutʲɪ] 'to cut' and *bjaurùs* [bʲjɛu'rʊs] 'ugly'. Earlier sequences of dental stop + *i̯* have developed into the affricates [t͡ʃʲ] and [d͡ʒʲ], orthographically *č*(*i*) and *dž*(*i*), as in *čià* (**ti̯a*) 'here' and *mẽdžias* (**medi̯as*) 'woods'. The distinctive palatalization of the remaining consonants is marked orthographically by a following *i*, as in *siū́ti* ['sʲū́ːtʲɪ] 'to sew' and *liáudis* ['lʲáudʲɪs] 'people'.

Morphosyntactic Features

The Noun

Lithuanian has preserved the Baltic stem classes and their declensional endings rather well, giving the noun a relatively archaic appearance. Six case forms are distinguished in the singular and plural (a dual is attested for certain case forms in dialects and older texts): (1) nominative (for example, in the singular, the *o*-stem *nãmas* 'house', *ā*-stem *rankà* 'hand', *i*-stem *akìs* 'eye', and *u*-stem *sūnùs* 'son'), (2) genitive (*nãmo*, *rañkos*, *akiẽs*, and *sūnaũs*), (3) dative (*nãmui*, *rañkai*, *ãkiai*, and *sū́nui*), (4) accusative (*nãmą*, *rañką*, *ãkį*, and *sū́nų*), (5) instrumental (*namù*, *rankà*, *akimì*, and *sūnumì*), and (6) locative (*namè*, *rankojè*, *akyjè*, and *sūnujè*). In addition, a special vocative form is used in the singular, as in *Jõnai!* (nominative *Jõnas* 'John') and *Birùte!* (nominative *Birùtė*).

The adnominal genitive is typically preposed, as in *tėvo nãmas* 'of-father house' ('father's house') and *lietùvių kalbà* 'of-Lithuanians language' ('Lithuanian language'). The genitive also occurs in partitive expressions, both positive, as in *miškè yrà vilkų* 'in-the-woods there-are wolves (genitive)', and negative, as in *nėrà žuviẽs* 'there-is-no fish (genitive)'. The locative case is used without a preposition, as in *Vìlniuje* 'in Vilnius'; historically this represents an inessive, the remnant of a more complex system of local cases formed with postpositions. These cases included an adessive, illative, and allative, some of which (particularly the illative) are still found dialectally.

Nouns are marked for gender (masculine and feminine) through distinctive desinences and adjectival concord, as in *gẽras tẽvas* 'good father' and *gerà mótina* 'good mother'. In an innovation shared with Latvian, proto-Baltic neuter gender was lost; neuters typically became masculine, as in *šiẽnas* 'hay' (masc.) and Old Church Slavonic *sěno* (neut.). The category of definiteness is marked within adjectives by the historical affixation of a pronominal *-i̯-* element to the indefinite form, as in indefinite *naũjas* (masc.), *naujà* (fem.) 'new' vs. definite *naujàsis* (i.e., *naujas* + *jis*) (masc.), *naujóji* (fem.).

The Verb

The Lithuanian verb marks present, past, and future tense forms. The present tense has three conjugation patterns, illustrated by *lìpti* 'to climb' (first conjugation, stem in *a*), *mylė́ti* 'to love' (second conjugation, stem in *i*), and *skaitýti* 'to read' (third conjugation, stem in *o*): 1SG (*aš*) *lipù*, *mýliu*, *skaitaũ*; 1PL (*mes*) *lìpame*, *mýlime*, *skaĩtome*; 2SG (*tu*) *lipì*, *mýli*, *skaitaĩ*; 2PL (*jūs*) *lìpate*, *mýlite*, *skaĩtote*; 3SG/PL (*jis/jie*) *lìpa*, *mýli*, *skaĩto*. The past tense has two patterns, illustrated by *lìpti* 'to climb' (stem in *o*) and *skaitýti* 'to read' (stem in *ė*): 1SG (*aš*) *lipaũ skaičiaũ*; 1PL (*mes*) *lìpome, skaĩtėme*; 2SG (*tu*) *lipaĩ, skaiteĩ*; 2PL (*jūs*) *lìpote, skaĩtėte*; and 3SG/PL (*jis/jie*) *lìpo, skaĩtė*. A frequentative past is formed by adding the suffix *-dav-* (plus *o*-stem endings) to the infinitive stem, as in *jis skaitýdavo* 'he used to read, would read' (*skaitýti* 'to read'). The future is formed by adding *-s-* and the present-tense person endings to the infinitive stem, *lìpti* 'to climb': 1SG (*aš*) *lìpsiu*, 1PL (*mes*) *lìpsime*, 2SG (*tu*) *lìpsi*, 2PL (*jūs*) *lìpsite*, and 3SG/PL (*jis, jie*) *lìps*. As the various examples demonstrate, number is not marked in the third person, a characteristic feature of Baltic.

Lithuanian shows a fondness for participles and gerunds, in both colloquial and written styles. Among the more typical participles (which decline like adjectives) are the present active (*rašą̃s*, stem *rãšant-*, infinitive *rašýti* 'to write'), past active ([*pa*]*rãšęs*, stem ([*pa*]*rãšius-*), present passive (*rãšomas*), and past passive (*parašýtas*). The past active

participle is used, together with a finite form of the verb 'to be,' to form a system of perfect tenses, as in *aš esù* (*pa*)*rãšes* (masc.)/(*pa*)*rãšiusi* (fem.) 'I have written' and *aš buvaũ* (*pa*)*rãšęs* (masc.)/(*pa*)*rãšiusi* (fem.) 'I had written'. Passive constructions are formed with the verb 'to be' and the corresponding passive participle, as in *knygà bùvo rãšoma* 'the book was being written' and *knygà bùvo parašýta* 'the book was/had been written'. The language retains a reflex of an earlier dative absolute in gerundive constructions such as *sáulei tẽkant* 'as the sun is/was rising' ('to-the-sun rising').

Lexicon

Lithuanian has long felt the lexical influence of neighboring Slavic languages. Early East Slavic borrowings into Lithuanian include *tuřgus* 'market' and *krìkštas* 'baptism' (Old Russian *tъrgъ* 'market' and *krъstъ* 'cross'). Among East Slavic borrowings from the time of the Grand Duchy are *knygà* 'book' and *blỹnas* 'pancake' (Russian *kníga* and *blin*). A significant number of Polish borrowings began to appear in Lithuanian in the 17th and 18th centuries, among them *arbatà* 'tea' and *cùkrus* 'sugar' (Polish *herbata* and *cukier*). Since the late 19th century, language reformers have succeeded in replacing many earlier borrowings with native words known from dialects and Old Lithuanian texts; for example, the native *laĩkas* 'time' was normalized in place of *čẽsas* (Russian *čas*), and *pasáulė* 'world', in place of *svíetas* (Russian *svet*). During this time, a number of neologisms took root, such as *akiniaĩ* 'eyeglasses' (*akìs* 'eye') and *mokyklà* 'school' (*mok-* 'teach, learn' + *-ykl-* 'place where').

Lithuanian Lexicography

A Veisbergs, Riga, Latvia

© 2006 Elsevier Ltd. All rights reserved.

The first trilingual Polish–Latin–Lithuanian dictionary was Konstantinas Sirvydas' *Dictionarium trium linguarum* (1620), and republished several times (most recently by Pirmasis, 1979). This was followed by several bidirectional Lithuanian–German dictionaries – Haack (1739) aimed at theology students and Ruigys (1747) with an input of vernacular language. The latter was in 1800 further improved by Milkus' *Littauisch–Deutsches und Deutsch–Littauisches Woerterbuch*. The living Lithuanian vernacular language was covered more fully in a trilingual explanatory dictionary by Juška (1897).

Further progress was made with a card index initiated by Kazimieras Būga, starting in 1902. The task was continued from 1930 by an editorial board under Juozas Balčikonis and continued to the present day (changing editorial policies several times) – 5 million entries, including also spoken language, dialects, and various styles. The work based on citations resulted in a 20-volume dictionary of the Lithuanian language (*Lietuvių kalbos žodynas*, 1968–2002) covering the years 1547–2001. Supplements are being compiled and an electronic version is being prepared.

The *Modern Lithuanian Dictionary* (*Dabartines*, 2002) also has an online version. A new *Dictionary of the standard Lithuanian language* is being compiled – for the general public – descriptive and normative.

There is a modern and good dictionary of synonyms (*Sinonimų*, 2002) and a big and new dictionary of phraseology (*Frazeologijos*, 2001) as well as as a dictionary of collocations (in electronic form only) based on a corpus of the contemporary Lithuanian language (100 million running words).

Several corpora exist; one is generally accessible. Though no dictionary has been based on them, there is a 1-million-word morphologically annotated corpus and three parallel corpora of the same size for

participle is used, together with a finite form of the verb 'to be,' to form a system of perfect tenses, as in *aš esù* (*pa*)*rãšes* (masc.)/(*pa*)*rãšiusi* (fem.) 'I have written' and *aš buvaũ* (*pa*)*rãšęs* (masc.)/(*pa*)*rãšiusi* (fem.) 'I had written'. Passive constructions are formed with the verb 'to be' and the corresponding passive participle, as in *knygà bùvo rãšoma* 'the book was being written' and *knygà bùvo parašýta* 'the book was/had been written'. The language retains a reflex of an earlier dative absolute in gerundive constructions such as *sáulei tẽkant* 'as the sun is/was rising' ('to-the-sun rising').

Lexicon

Lithuanian has long felt the lexical influence of neighboring Slavic languages. Early East Slavic borrowings into Lithuanian include *tuřgus* 'market' and *krìkštas* 'baptism' (Old Russian *tъrgъ* 'market' and *krъstъ* 'cross'). Among East Slavic borrowings from the time of the Grand Duchy are *knygà* 'book' and *blỹnas* 'pancake' (Russian *kníga* and *blin*). A significant number of Polish borrowings began to appear in Lithuanian in the 17th and 18th centuries, among them *arbatà* 'tea' and *cùkrus* 'sugar' (Polish *herbata* and *cukier*). Since the late 19th century, language reformers have succeeded in replacing many earlier borrowings with native words known from dialects and Old Lithuanian texts; for example, the native *laĩkas* 'time' was normalized in place of *čẽsas* (Russian *čas*), and *pasáulė* 'world', in place of *svíetas* (Russian *svet*). During this time, a number of neologisms took root, such as *akiniaĩ* 'eyeglasses' (*akìs* 'eye') and *mokyklà* 'school' (*mok-* 'teach, learn' + *-ykl-* 'place where').

The living Lithuanian vernacular language was covered more fully in a trilingual explanatory dictionary by Juška (1897).

Further progress was made with a card index initiated by Kazimieras Būga, starting in 1902. The task was continued from 1930 by an editorial board under Juozas Balčikonis and continued to the present day (changing editorial policies several times) – 5 million entries, including also spoken language, dialects, and various styles. The work based on citations resulted in a 20-volume dictionary of the Lithuanian language (*Lietuvių kalbos žodynas*, 1968–2002) covering the years 1547–2001. Supplements are being compiled and an electronic version is being prepared.

The *Modern Lithuanian Dictionary* (*Dabartines*, 2002) also has an online version. A new *Dictionary of the standard Lithuanian language* is being compiled – for the general public – descriptive and normative.

There is a modern and good dictionary of synonyms (*Sinonimų*, 2002) and a big and new dictionary of phraseology (*Frazeologijos*, 2001) as well as as a dictionary of collocations (in electronic form only) based on a corpus of the contemporary Lithuanian language (100 million running words).

Several corpora exist; one is generally accessible. Though no dictionary has been based on them, there is a 1-million-word morphologically annotated corpus and three parallel corpora of the same size for

three different pairs of languages: Czech, English, German, and Lithuanian.

A typical Lithuanian dictionary is first and foremost a bilingual dictionary. The contemporary bilingual dictionary scene offers a great number of dictionaries and a great number of languages covered: apart from the traditional ones, also Japanese, Italian, Spanish, Latin (Kuzavinis, 1996), and Polish (Vaitkevičiūtė, 1979).

English–Lithuanian dictionaries started as émigré products. The most important are a large Lithuanian–English dictionary (Piesarskas, 2002) and a large two-volume English-Lithuanian dictionary (Piesarskas, 2004).

The German connection is best covered by Križinauskas (2001, 2004), French by Juškiene (1997) and Karsavina (1992).

There is a multitude of terminological dictionaries and glossaries (e.g., computing, textiles, agriculture, roads, hunting, sports, engineering, law etc.). Twenty-one terminological dictionaries were scanned and supplied with a query system, thus forming an online terminological database. These are mostly multilingual (usually Lithuanian, Russian, or English) and have unfortunately only a small circulation. Parliament has an online EUROVOC dictionary, which, as stipulated by law, collects a record of all technical terminology.

Among other sources one could also mention dictionaries of verbal associations, a dictionary of nicknames, proper names, first names, place names, hydronyms, mistakes, reverse dictionary, several dialects, accentuation, spelling and punctuation, frequency dictionary (based on a 1-million-word corpus, annotated morphologically), several contemporary dictionaries of foreign words, but no modern dictionary of etymology and no slang dictionary (a dictionary of curse words is under preparation).

Summing up, it can be said that the Lithuanian dictionary scene is vibrant and unexpectedly well developed for a small nation of 3.3 million people.

Liu Xie (ca. 500)

Y Gu, Chinese Academy of Social Sciences, Beijing, China

© 2006 Elsevier Ltd. All rights reserved.

Liu Xie (ca. 465–522 A.D.) was a native of what is now Lü County, Shandong Province. Tradition says that he was a descendant of the Lord of Qi, Liu Fei, who was a son of Liu Bang, the first emperor of the Former Han dynasty (206 B.C.–25 A.D.). It is however certain that his father Liu Shang was a ranking officer in the military, but he died when Liu Xie was still young. He was reared in poverty by his mother. It was said that he was so poor that he never got married. His bachelor life was perhaps also due to his 10 years of close association with a monk, who was not only

versed in Buddhism, but also in Confucian classics. Liu Xie was said to have taken part in editing Buddhist sutras in Dinglin Monastery. He is best known for his monumental work *Wenxin diaolong* ('The literary mind and the carving of dragons').

Liu Xie completed his monumental work *Wenxin diaolong* ('The literary mind and the carving of dragons') around 501, when he was little known. Tradition reports that he carried the manuscript, waiting for Shen Yue's (441–513 A.D., the most influential literary critic of the time) cart to pass by. Eventually he succeeded. With Shen Yue's recommendation he soon established his reputation. Liu Xie was said to be a prolific writer, but only a few of his works survive.

In Chinese academic circles, *Wenxin diaolong* is a work not without controversy. The dispute is not over its academic quality, which is unanimously recognized as first class by any standards, but over its disciplinary classification. Literary critics claim that it is a milestone in literary criticism, whereas rhetoricians argue that it is primarily the first systematic treatment of rhetoric in Chinese history. The controversy is quite understandable, and actually to be expected on the grounds that rhetoric and literary criticism are intrinsically related to each other. It is argued by some that the embryonic conception of Chinese rhetoric was detectable even in oracle bone inscriptions. But it had remained fragmented for about a thousand years before Liu Xie's monumental work. From the point of view of rhetoric, he made a ground-breaking study of discourse genres, style, and many figures of speech. He also analyzed what would be labeled as issues of invention and disposition in Western rhetoric.

There is a rich literature of textual studies of the work. Present-day editions include Fan Wenlan's *Wenxi diaolong zhu*, Yang Mingzhao's *Wenxin diaolong jiaozhu*, and Zhou Zhenfu's *Wenxin diaolong zhushi*. Vincent Yu-Chung Shih's 1983 *The literary mind and the carving of dragons* is a bilingual English-Chinese version with annotations.

Loanword Phonology

E Broselow, Stony Brook University, Stony Brook, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

The term 'loanword' is used for words (and sometimes phrases) borrowed from one language into another. The pronunciation of borrowed words is affected by many factors, including the nature and degree of contact between the lending and the borrowing communities (Haugen, 1950; Weinreich, 1953), the prestige of the languages in contact, the time course of borrowing, and the medium of transmission. Loanword pronunciation patterns may range from preservation of all or most features of the original (most often when borrowers are fluent in the foreign language or are members of a group of experts using specialized vocabulary) to fairly drastic alterations (when the new words become fully nativized or integrated into the borrowing language). 'Ear borrowings' tend to reflect pronunciation more faithfully than orthography (e.g., the orthographic but unpronounced 't' of 'Christmas' is not realized in Japanese [kurisumasu]), whereas 'eye borrowings' tend to reflect orthography (as in Hawaiian [hi:meni] 'hymn'). Although the pronunciation of borrowed words may be complicated by many extralinguistic factors, systematic patterns often emerge that provide potentially crucial insight into the grammar of the borrowing language as well as into deeper questions of the relationship between perception and production, the role of frequency of different structure types in the data available to language learners and users, and the extent to which the formation of a grammar is shaped by universal and possibly innate principles.

Loanword Phonology

E Broselow, Stony Brook University, Stony Brook, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

The term 'loanword' is used for words (and sometimes phrases) borrowed from one language into another. The pronunciation of borrowed words is affected by many factors, including the nature and degree of contact between the lending and the borrowing communities (Haugen, 1950; Weinreich, 1953), the prestige of the languages in contact, the time course of borrowing, and the medium of transmission. Loanword pronunciation patterns may range from preservation of all or most features of the original (most often when borrowers are fluent in the foreign language or are members of a group of experts using specialized vocabulary) to fairly drastic alterations (when the new words become fully nativized or integrated into the borrowing language). 'Ear borrowings' tend to reflect pronunciation more faithfully than orthography (e.g., the orthographic but unpronounced 't' of 'Christmas' is not realized in Japanese [kurisumasu]), whereas 'eye borrowings' tend to reflect orthography (as in Hawaiian [hi:meni] 'hymn'). Although the pronunciation of borrowed words may be complicated by many extralinguistic factors, systematic patterns often emerge that provide potentially crucial insight into the grammar of the borrowing language as well as into deeper questions of the relationship between perception and production, the role of frequency of different structure types in the data available to language learners and users, and the extent to which the formation of a grammar is shaped by universal and possibly innate principles.

Loan Adaptation

One of the best studied aspects of loanword phonology is the process of altering borrowed words to satisfy the borrowers' native language constraints on sounds, sound combinations, and prosodic organization of words. One obvious problem is the occurrence in foreign words of sounds that are lacking in the borrowing language. This situation frequently gives rise to the process of phoneme substitution, the replacement of foreign sounds by native language phonemes (the set of contrasting sounds that may be used to encode contrasts in meaning). Thus, borrowings from English, which employs more than 30 phonemes, into Hawaiian, with only 13 contrasting sounds, may exhibit extensive alteration; for example, both 'Katherine' and 'gasoline' emerge as [kakalina], with [r], [g], [θ], [s], [æ], and [ə] all undergoing substitution (Elbert and Pukui, 1986). A more subtle problem arises when the foreign sound does occur in the borrowing language, but only in restricted contexts. For example, in Ganda, [l] never appears following a front vowel [i] or [e], whereas [r] occurs only after front vowels. A Ganda speaker can therefore pronounce both [r] and [l], but only in specific contexts, leading to the adaptation of English 'railway' as Ganda [lerwe] (Halle and Clements, 1993).

A second motivation for the alteration of borrowed words stems from the borrowing language's phonotactics, or restrictions on combinations of sounds. The bisyllabic word 'Christmas' is realized with five syllables in Japanese ([kurisumasu]) and in Samoan ([kilisimasi]), reflecting the requirements of the borrowing languages that all or most consonants be followed by a vowel. Similarly, loss of the [r] in the Navajo pronunciation [keʃmiʃ] can be traced to the impossibility of consonant sequences at the beginning of a Navajo word or syllable (www.santas.net/howmerrychristmasissaid.htm).

Restrictions on the shape and organization of words are additional factors motivating the alteration of loanwords. Many languages adhere to a minimal word size and will augment borrowed words that fall short. For example, 'bomb' is adapted in Selayarese as [boʔoŋ] (Broselow, 1999); the change of the final [m] to [ŋ] is dictated by the impossibility of word-final [m], but the addition of a vowel and glottal stop (resulting in [boʔoŋ] rather than *[boŋ]) is motivated by the Selayarese requirement that all words must contain at least two syllables. In addition, most languages use the word as the basis for characteristic patterns of stress or pitch, and loans are often adapted to conform to these patterns. For example, whereas the most prominent stress falls on the word-initial syllable in English 'Christmas,' the major stress of Hawaiian [kalikimáka] falls on the prefinal syllable, in accord with Hawaiian principles of stress placement. In borrowing from stress-based languages into languages in which words are characterized by lexically assigned tonal or pitch patterns, the original stress pattern may be reinterpreted as a pitch-based pattern. Thus, in Cantonese a high tone is generally assigned to the syllable carrying main stress in English, falling on the initial syllable of [fasan] 'fashion' and on the final syllable of [sytka] 'cigar' (Silverman, 1992).

Linguists have traditionally looked to loanword adaptation as a probe into the particular grammars of borrowing languages as well as into the general structure of phonological grammars. In particular, the alterations of borrowed words may provide evidence for phonological rules or constraints that cannot be motivated by native language alternations because the relevant structural types simply do not occur in the native language vocabulary. For example, in analyzing Nupe (Nupe-Nupe-Tako), in which labialized consonants occur only before rounded vowels or before [a], Hyman (1970) argued that the [a] following a labialized consonant is derived from underlying [ɔ], which triggers labialization on the preceding consonant before undergoing a rule of absolute neutralization. Since [ɔ] never appears on the surface in Nupe, the support for a rule transforming [ɔ] to [a] comes from adaptation of Yoruba words such as [kɔbɔ] 'penny' as Nupe [k^{w}ab^{w}a] (with HL tone on both forms). More recently, as much phonological research has moved toward models of grammar consisting not of rules but of surface-oriented constraints, the lack of particular structures in both native and borrowed vocabulary can be seen as having the same source, a set of universal markedness constraints (Jacobs and Gussenhoven, 2000; Yip, 1993).

Problems in Loanword Phonology

Choice of Strategies for Loanword Adaptation

The motivation for changing the structure of borrowed words can often be found in the restrictions of the borrowing language, which define targets for adaptation. However, precisely because the native language often lacks forms that require repair, the native language grammar may not provide guidance in different ways of reaching that target (e.g., in choice of substitute for a foreign sound). What, then, determines borrowers' choice of repair strategy?

One possibility is that the means used to adapt loanwords is largely a function of the native language grammar (Jacobs and Gussenhoven, 2000; Paradis and LaCharité, 1997). However, it is often difficult

to explain how the data of the borrowers' native language could have led them to converge on a particular repair strategy when their native language lacks structures that require repair (Broselow, 1999; Peperkamp and Dupoux 2003). In fact, the repairs used in loanwords are sometimes different from those used for similar native vocabulary. For example, in Malayalam single voiceless stops may not occur intervocalically. In native vocabulary, an intervocalic stop becomes voiced, while in Malayalee English an intervocalic stop is realized as a voiceless geminate, as in [beekkar] 'baker' (Mohanan and Mohanan, 2003).

If the strategies for loanword adaptation are not entirely a function of the borrowing language grammar, perhaps they reflect the emergence of universal preferences for particular types of structures. For example, both Shinohara (2004) and Kenstowicz and Sohn (2001) found evidence that the preferred position for the accented syllable in words borrowed into Japanese and into North Kyungsang Korean is on a heavy prefinal syllable, a familiar pattern in stress systems of the world. Similarly, particular types of repairs might be universally preferred; for example, Fleischhacker (2001) found that in many languages that prohibit consonant sequences at the beginning of a word, a vowel is inserted in loanwords before a sequence of [s]-stop but between the two consonants otherwise (compare Egyptian Arabic [iski:] 'ski' and [bilastik] 'plastic' (Broselow, 1992) and Hindi [iskul] 'school' and [pIliz] 'please' (Singh, 1985)). Fleischhacker argued that loan adaptation is guided by a universal 'perceptual mapping' that dictates what sorts of repairs result in the greatest perceptual similarity to the original (see also Kang, 2003; Kenstowicz, 2001, 2003).

However, many cases of loanword adaptation are not obviously explainable as reflexes of universal cross-linguistic preferences. For example, it is generally assumed that in phoneme substitution, the 'closest' native language phoneme is substituted for the foreign phoneme. However, languages may choose different segments as 'closest': the [s] in 'Christmas' is replaced by [k] in Hawaiian [kalikimaki] and by [h] in Maori [kirihimete], although both languages include [k] and [h] (but not [s]) in their inventories. Languages may also choose different strategies for bringing foreign words into line with native language allophonic restrictions. In Japanese [s] and [ʃ] are in complementary distribution, with [ʃ] occurring only before [i]. The impossible sequence [ʃe] is transformed in (nativized) borrowed words by changing the consonant, as in [sepa:do] 'shepherd' (Ito and Mester, 1995a, 1995b). In Nupe, however, which has similar distribution of [s] and [ʃ], an illegal sequence is repaired by changing the vowel to [i], as in the rendering of Hausa [ʃu:gaba] (with LLH tone) 'leader' as Nupe [ʃi:gaba] (with LLM tone; Hyman, 1970). Similarly, although the insertion of vowels in the various realizations of 'Christmas' – Japanese ([kurisumasu]), Hawaiian [kalikimaki], Samoan ([kilisimasi]), and Maori [kirihimete] – is clearly motivated by the need to bring borrowed words into conformity with native language syllable structure requirements, it is not clear why the quality of the inserted vowels should differ from language to language. Nor is it clear why these languages should choose vowel insertion, whereas Navajo, for example, deletes a consonant in [keʃmiʃ]. Different borrowing languages may also choose different strategies for upholding native language word stress requirements. In Hawaiian, preferred stress patterns are implemented in borrowings by simply reassigning the main stress to the appropriate syllable of the loanword (as in [kalikimáki]), whereas speakers of Huave maintain the native language requirement that stress normally falls on the word-final syllable by deleting poststress material, so that Spanish [kardúmen] 'flock' is adapted as [kardúm] (Davidson and Noyer, 1996).

Thus, borrowers of different language backgrounds may choose different repair strategies for similar foreign structures, even when both native languages appear to provide similar options and when the grammar of the native language appears to provide no guidance in choosing among options, raising the issue of the learnability of loan adaptation pattens (Broselow, 1999; Peperkamp, 2004). The principles determining the choice of repair constitute an important research problem for linguists, with proposals ranging from the claim that all loan adaptation is a function of misperception (Peperkamp and Dupoux, 2003) to proposals making reference to various factors: perception, production, and the nature of the data available to borrowers.

Preservation of Foreign Features

A related question in loanword adaptation concerns why some features of borrowed words are changed to fit the native language constraints while others are maintained intact. Not all loanwords are fully adapted, and indeed over time the borrowing language may come to incorporate foreign structures, as in the English acceptance of [v] as an independent phoneme rather than the intervocalic reflex of [f] under the influence of French. In many languages, some sets of words retain foreign elements, resulting in what Ito and Mester (1995a, 1995b) called lexical strata: groups of words obeying distinct (but overlapping) sets of constraints. For example, in the core

vocabulary of Japanese both [si] and [ti] sequences are impossible, and these sequences in the most nativized loanwords undergo palatalization: [ʃifu:do] 'seafood' and [tʃi:m] 'team.' In a more peripheral stratum, however, only the constraint against [si] is upheld, resulting in pronunciations such as [ʃitibanku] 'Citibank.' Furthermore, nonnativized vocabulary may contain both [si] and [ti] sequences. There are no words, however, like hypothetical *[sitʃibanku], where [si] is tolerated but [ti] is not. Thus, although both structures are equally foreign to core Japanese vocabulary, one is more readily accepted in borrowed words.

The principles determining which foreign structures are more subject to preservation are yet to be understood. One family of proposals correlates the likelihood of preservation of foreign structures to the extent to which their individual articulatory components are part of the borrowing language system. Thus, Maddieson (1986) discussed evidence that a foreign phoneme is more likely to be incorporated into the borrowing language system if it fills some gap in the native language phoneme inventory; for example, [p] is more likely to be borrowed if the language already has a voiced labial stop [b] and if it has voiceless/voiced oppositions at other places of articulation ([t/d] and [k/g]). Similarly, Ussishkin and Wedel (2003) argued that medial consonant sequences are more likely to be tolerated in loanwords if the borrowing language allows word-final consonants (and therefore has consonant sequences across word boundaries). Thus, although neither Puluwat (Puluwatese) nor Tongan have consonant sequences within words, Puluwat does allow word-final consonants (and therefore consonant sequences across word boundaries), and in borrowed words, word-internal consonant sequences are much more likely to be preserved in Puluwat ([kapsajis] 'capsize') than in Tongan ([kakatisi] 'cactus'). Other factors that may be implicated include simple frequency of foreign structures and the acoustic similarities between the native and foreign structures; borrowers may identify certain foreign phonemes, for example, as variants of native language phonemes.

Although the patterns of loanword adaptation raise numerous questions, it is clear that they provide an important testing ground for hypotheses concerning how language is learned and how language is used.

Localization

G Budin, University of Vienna, Vienna, Austria

© 2006 Elsevier Ltd. All rights reserved.

Defining and Distinguishing Key Terms

Localization refers to the processes of preparing and adapting products linguistically and culturally for their sale and use in a specific locale, i.e., in a language community in a country or region of the world. A 'locale' is a virtual rather than a physical location, where a group of people share certain cultural and linguistic conventions in a consistent way so that the localization industry is able to identify the locale and distinguish it from other, maybe neighboring, locales (e.g., British English vs. American English). Traditionally, the concept of localization is distinguished from the concept of internationalization, i.e., the process of designing products in a generic way so that they can be localized easily and quickly. The process of internationalization is thus a prerequisite to localization. A more comprehensive concept is that of globalization. Besides its generic socioeconomic and political meaning, the term refers to the overall strategic planning level of 'going global' with one's own products. On the operational level, it refers to the process of internationalization and subsequent localization and translation work. Due to the worldwide process of economic globalization, the demand for localization, internationalization, and translation has been growing continuously over the past decades. Translation is a core process in the localization process because it focuses on crossing borderlines between languages and cultures and because it involves the comparison of cultural specificities of different locales, language communities, countries, etc., as well as the subsequent choice of communicative means in a target language or culture to adequately express the content of text available in a source language or culture.

What Is Localized and How Is It Done?

Although localization has been successfully practiced for a long time in almost all spheres of trade and industry, the term 'localization' has been used more recently mainly in the contexts of the computer industry and of Internet- and Web-based trade. The localization of software products and of websites reflects the growing economic importance of localization in world trade. For the purpose of software localization, the program code has to be separated as nonlocalizable components from the user interface in general and from individual cultural elements to be localized in particular. While localization engineering includes the efficient use of localization tools, localization management focuses on the translation and cultural adaptation of user manuals, online help, and other types of software documentation. A 'locale' is a virtual rather than a physical location, where a group of people share certain cultural and linguistic conventions in a consistent way so that the localization industry is able to identify the locale and distinguish it from other, maybe neighboring, locales (e.g., British English vs. American English). Traditionally, the concept of localization is distinguished from the concept of internationalization, i.e., the process of designing products in a generic way so that they can be localized easily and quickly. The process of internationalization is thus a prerequisite to localization. A more comprehensive concept is that of globalization. Besides its generic socioeconomic and political meaning, the term refers to the overall strategic planning level of 'going global' with one's own products. On the operational level, it refers to the process of internationalization and subsequent localization and translation work. Due to the worldwide process of economic globalization, the demand for localization, internationalization, and translation has been growing continuously over the past decades. Translation is a core process in the localization process because it focuses on crossing borderlines between languages and cultures and because it involves the comparison of cultural specificities of different locales, language communities, countries, etc., as well as the subsequent choice of communicative means in a target language or culture to adequately express the content of text available in a source language or culture.

What Is Localized and How Is It Done?

Although localization has been successfully practiced for a long time in almost all spheres of trade and industry, the term 'localization' has been used more recently mainly in the contexts of the computer industry and of Internet- and Web-based trade. The localization of software products and of websites reflects the growing economic importance of localization in world trade. For the purpose of software localization, the program code has to be separated as nonlocalizable components from the user interface in general and from individual cultural elements to be localized in particular. While localization engineering includes the efficient use of localization tools, localization management focuses on the translation and cultural adaptation of user manuals, online help, and other types of software documentation. Website

localization has become a critical success factor for companies that use the Internet as a marketing instrument and that invest in e-commerce portals. The simultaneous launch of products in culturally and linguistically different markets (locales) requires the implementation of globalization strategies in general and of internationalization processes in particular.

Who Is Active in Localization?

The complex tasks described above are increasingly carried out by localization professionals who are specifically educated and trained for such activities. The localization industry has developed professional profiles and specific roles in project teams, with best practices, success stories, quality models, and industry standards, and with professional organizations, such as the Localization Industry Standards Association (LISA), that organize symposia and workshops and that publish newsletters and standards documents. Localization has also become a topic of research activities in language engineering, translation studies, computer science, and other relevant disciplines. Courses and education programs are increasingly offered by academic institutions and by professional organizations (e.g., the Localization Research Centre at Trinity College in Dublin, Ireland). Localization service providers include small local businesses and large companies that act as global players in this competitive industry. For further reading, please consult the bibliography, which contains references to textbooks such as Bernd Esselink's guide to software localization, as well as the list of Web references.

Locke, John (1632–1704)

V Raby, Université de Reims-Champagne-Ardenne, Reims, France

© 2006 Elsevier Ltd. All rights reserved.

John Locke was born on August 28, 1632 in Wrington, Somerset, to a Puritan family. He studied at Westminster School and in Oxford, where he was appointed as a college tutor in 1661. During these years, his interest for medicine led him to the study of natural philosophy. Beginning in 1667, he served as secretary, physician, and political advisor to Lord Ashley, future Earl of Shaftesbury. He was elected a Fellow of the Royal Society. Locke came to France in 1673, after Shaftesbury's resignation as lord chancellor. There he worked on the study of philosophy, and met and read Cartesians and Gassendists. He returned to England in 1679 and became involved in politics, until his departure for Holland as a political refugee in 1683. He came back to England after the reign of James II in 1689 and spent his later years preparing his publications, the *Essay*, along with works about political theory, monetary problems, education, and theology. He died on October 28, 1704 in Oates, Essex.

His contribution to linguistics is mainly located in Book III of *An essay concerning human understanding* (1690), titled 'Of words.' The general purpose of the *Essay* was to build an empirical theory of knowledge, assuming that there were no 'innate ideas,' and that all types of 'ideas' originated from

Locke, John (1632–1704)

V Raby, Université de Reims-Champagne-Ardenne, Reims, France

© 2006 Elsevier Ltd. All rights reserved.

John Locke was born on August 28, 1632 in Wrington, Somerset, to a Puritan family. He studied at Westminster School and in Oxford, where he was appointed as a college tutor in 1661. During these years, his interest for medicine led him to the study of natural philosophy. Beginning in 1667, he served as secretary, physician, and political advisor to Lord Ashley, future Earl of Shaftesbury. He was elected a Fellow of the Royal Society. Locke came to France in 1673, after Shaftesbury's resignation as lord chancellor. There he worked on the study of philosophy, and met and read Cartesians and Gassendists. He returned to England in 1679 and became involved in politics, until his departure for Holland as a political refugee in 1683. He came back to England after the reign of James II in 1689 and spent his later years preparing his publications, the *Essay*, along with works about political theory, monetary problems, education, and theology. He died on October 28, 1704 in Oates, Essex.

His contribution to linguistics is mainly located in Book III of *An essay concerning human understanding* (1690), titled 'Of words.' The general purpose of the *Essay* was to build an empirical theory of knowledge, assuming that there were no 'innate ideas,' and that all types of 'ideas' originated from

sensation and reflection. This lead to the distinction between names for simple ideas, and names for mixed modes and substances. The significance of simple ideas could be secured by acts of ostension toward single perception, but the significance of the latter only relies on their definition. Locke insisted that, even if this could not be improved upon, we must always remember that the meaning of words resulted from our own 'voluntary imposition.' Words were signs of our internal conceptions and stood as 'marks' for ideas. This hypothesis was not new, but Locke added that this conception might differ from one individual to the other, because the meaning of words depended entirely on personal knowledge. This was particularly significant when it came to general terms. General terms did not refer to anything but were necessary to represent abstract, general ideas. They resulted from the activity of understanding, which 'sorts' particular things together according to their similarities and 'ranks' them under general names. Consequently, the question was to know how could one be sure to transmit, by means of conventional linguistic signs, the 'determinate ideas' required for knowledge and reasoning. This analysis led Locke to diagnose 'imperfections' in the use of language, and give remedies that every careful speaker should use to avoid most of these defaults.

The idea that language may condition thoughts was further defined by Condillac. It has also been expanded upon in the field of language acquisition and the study of relationships between language and culture. Book III of the *Essay* deals mostly with the semantics of common names, but Locke also introduced, in Book IV, 21, a definition of *sémeiôtikè* as the 'doctrine of signs' and as the third kind of science, after *physica* and *practica*.

Lodwick, Francis (1619–1694)

C Neis, University of Potsdam, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

Francis Lodwick (1619–1694) was baptized on August 8, 1619 in London, where he was also buried on January 5, 1694. Lodwick [Lodowyck] attained important achievements in the domains of universal languages and phonetics.

His father was a refugee Flemish merchant, while his mother was a descendant of French Huguenots. During his lifetime Lodwick was engaged in trade between England and the continent and was a highly influential member of the Anglo-Dutch community in London. Most details about Lodwick's life are reported in the diary of Robert Hooke (1635–1703). In 1681, Lodwick was elected a member of the Royal Society. His writings attest to his interests in different fields, e.g., economy, politics, religion, and linguistics.

His upbringing at a Protestant refugee community might have aroused his interest in linguistic issues, especially his desire to invent a universal language suitable for international communication. Lodwick was probably the first man to publish a book on a universal written character and language, *A common writing*, which appeared in 1647. Lodwick's universal language project was influenced by Francis Bacon (1561–1626) and John Wilkins (1614–1672), who advocated the creation of a universal written 'character' that should have rendered communication possible between speakers of different languages. Lodwick, in his brief *A common writing* presented a universal language that contains a collection of words. These words are represented by non-verbal characters similar to arithmetic symbols that are useable in every language. Lodwick also suggested a dictionary containing primordial words and their derivations that can be gathered by the use of standardized diacritics.

A second and more fruitful attempt at the creation of a universal character is his *The ground-work, or foundation laid, (or so intended) for the framing of a new perfect language: and an universall or common writing. And presented to the consideration of the learned, by a well-willer to learning*. In this writing, published in 1652, Lodwick gave a more sophisticated solution to the problem of universal language as he tried to lay the foundation for a perfect new language suitable for the representation of the real order of nature. He suggested a scientific nomenclature with reference to the qualities of things. The main part of the text, however, is devoted to the project of a grammar that would reduce the multiplicity of rules in natural languages. One of his most striking solutions is the introduction of a universal word-order. Lodwick's third suggestion for a universal language was published in 1686: *An essay towards an universal alphabet*. Although Lodwick's attempts to create a universal language were never realized, his writings had a deep impact on Wilkins; in his *Essay towards a real character, and a philosophical language* (1668) he acknowledged his debt to Lodwick.

Most of Lodwick's other writings, such as his earliest shorthand system for Dutch on phonetic principles, remained in manuscript form. Several manuscripts were published in the Royal Society's *Philosophical Transactions*, e.g., his scheme for a phonetic alphabet useable in every language.

Lodwick may be characterized as an original thinker and one of the leading figures of linguistic discussions in the 17th century.

Introduction

Theories of meaning and methods of linguistic analysis are key items in the agenda of contemporary analytic philosophy. Philosophical interest in language gained substantial impetus from developments in logic that took place in the latter half of the nineteenth century. It was at this time that the early modern conception of logic as an informal 'art of thinking' gave way to the contemporary conception of logic as a formally rigorous, symbolic discipline involving, *inter alia*, a mathematically precise approach to deductive inference. The systems of symbolic logic that emerged in the later stages of the nineteenth century were fruitfully applied in the logical regimentation of mathematical theories – analysis and arithmetic in particular – and logical analysis became the cornerstone of a general philosophical methodology for a number of influential figures in the first half of the twentieth century. Though the operative conception of logical analysis did not in every case treat language (or 'natural language') as the proper object of investigation, close connections between logic and language were stressed by virtually every proponent of the methodology. Our aim in this entry is to discuss these connections as they appear in the work of some of the eminent precursors and purveyors of the analytic tradition.

The Mathematicization of Logic: Leibniz and Boole

Early modern philosophers were typically antipathetic to the formal approach to logic embodied in Aristotle's doctrine of the syllogism and its Scholastic variants. Among the major figures of the early modern period, Gottfried Wilhelm Leibniz (1646–1716) is distinguished both for his respect for the Aristotelian tradition in logic and for his general emphasis on the importance of formal methods. Leibniz applauded Aristotle for being "the first to write actually mathematically outside of mathematics" (1696: 465). However, it was Leibniz's own works, rather than those of Aristotle or of contemporary Aristotelians, that in the period did most to advance the conception of logic as a kind of generalized mathematics.

Leibniz's logical work consists of a number of manuscripts, unpublished in his lifetime, in which he undertakes the construction of a logical calculus. In virtually all of these works, Leibniz represents judgments and logical laws in a quasi-arithmetical or algebraic notation and he assimilates processes of inference to known methods of calculation with numbers (e.g., by substitution of equals). Leibniz's motivation for this approach stemmed from his early project of a *lingua characteristica universalis* – a symbolic language geared to the logically perspicuous representation of content in all fields of human knowledge. According to Leibniz, the content of any judgment consists in the composition of the concepts arrayed in the judgment as subject and predicate. A judgment is *true* when the predicate concept is 'contained in,' or partially constitutive of, the subject concept. For example, the truth of the judgment that all men are rational consists in the fact that the concept *rational* is contained in the concept *man*, as per the traditional definition of 'man' as 'rational animal.' (For obvious reasons, Leibniz's conception of truth posed difficulties when it came to accounting for contingently true judgments, and the task of providing an account of contingency compatible with his conception of truth was one to which Leibniz devoted considerable philosophical attention.) All complex concepts can be parsed as conjunctions of concepts of lower orders of complexity down to the level of simple concepts that cannot be further analyzed. Leibniz's various schemes for a universal characteristic were predicated on the idea that containment relations among concepts could be made arithmetically tractable given an appropriate assignment of 'characteristic numbers' to concepts. For instance, in one such scheme Leibniz proposed that the relationship between complex concepts and their simple constituents be represented in terms of the relationship between whole numbers and their prime factors, thus capturing the unique composition of any complex from its primitive components (1679, 1679/1686). In this and similar ways, Leibniz sought to provide a basis for the view that inference, and the evaluation of truth more generally, could be carried out algorithmically – that is, as a mere process of calculation – by familiar arithmetical means.

By the 1680s Leibniz had grown pessimistic about the prospect of completing the project of the universal characteristic, and he turned his energies to the more confined task of devising an abstract logical calculus. Leibniz worked on a number of different versions of his logical calculus through the 1680s and 1690s. In each case he explained how standard propositional forms could be expressed in a quasi-algebraic

notation. He also laid down logically primitive laws pertaining to his formulas (what he called 'propositions true in themselves') and abstractly specified valid inferential transformations, usually in terms of a definition of 'sameness' in conjunction with principles pertaining to the substitutability of identicals. Though Leibniz's efforts at constructing a logical calculus were hampered by his view that all judgments ultimately reduce to a simple subject-predicate form – thus excluding primitive relational judgments – his emphasis on formal explicitness and mathematically exact symbolism stands as an anticipation of the main lines of development in formal logic in the following centuries.

Leibniz's mathematical approach to logic made little impression until the late nineteenth century, when his manuscripts were finally collected and published. By that time, however, the mathematical approach had gained momentum independently, largely on the basis of the work of George Boole (1815–1864). Boole shared with Leibniz the aim of devising an algebraic means of expressing relationships among terms figuring in propositions. However, Boole differed from Leibniz in treating the extensions of concepts (or classes), rather than concepts construed as attributes or 'intensions,' as the relevant propositional constituents. In *The laws of thought* (1854), Boole presented his class logic, which he called 'the logic of primary propositions,' as the first and fundamental division of his system. In the second part of the same work, Boole adapted the calculus of classes to a special interpretation that allows for the representation of logically compound propositions, or 'secondary propositions,' thereby unifying (after a fashion) the calculus of classes with a version of modern propositional calculus.

Boole's central idea is that an algebra of logic arises as an *interpretive variant* of standard numerical algebra when the latter is modified by a single principle that is naturally suggested by the logical interpretation of the symbolism. In Boole's class logic, letters (or 'literal symbols') are interpreted as standing for classes of things determined by some common attribute, with '1' standing for the universe class and '0' standing for the null class. Multiplication, addition, and subtraction operators are treated as standing for the operations of intersection, disjoint union, and difference (or 'exception') of classes, respectively. Primary propositions are then expressed as equations with appropriately formed class terms standing on either side of the identity sign. On the basis of this class-theoretic interpretation of the symbolism, Boole maintained that the logical calculus differs from ordinary numerical algebra only with respect to the characteristically *logical* law that, for any class x,

$$xx = x \text{ (x intersect x is x)}$$

which holds generally for class theoretic intersection but which holds for numerical multiplication only for $x = 0$ and $x = 1$. Having emphasized this difference, Boole observed that the laws and transformations of numerical algebra will be identical to those of an algebra of logic when the numerical values of literal symbols in the former are restricted to 0 and 1. Boole appealed to this formal analogy between the numerical and logical algebras in justifying his approach to inference, which he presented as a process of solving sets of simultaneous equations for unknowns by standard algebraic methods.

In *The laws of thought,* Boole transformed the calculus classes into a serviceable propositional calculus by interpreting his literal symbols over 'portions of time' during which elementary propositions are true, thus adapting the notation and methods designed for dealing with class relationships to the propositional case. Boole's appeal to portions of time reflected a somewhat puzzling endeavor to assimilate or reduce propositional logic to the kind of term logic embodied in his class calculus, and the artificiality of this approach was not lost on subsequent logicians both within and without the algebraic tradition. However, peculiarities of interpretation notwithstanding, Boole can be credited with the first systematic formulation of propositional logic and a commensurate expansion of the scope of formal logic in general. Moreover, his suggestion that propositional logic, class logic, and numerical algebra (suitably restricted) arise as interpretive variants of a single algebraic system anticipates subsequent developments in abstract algebra and (perhaps only dimly) modern model-theoretic methods in logic.

The contributions of Leibniz and Boole constitute beginnings in the fruitful deployment of artificial languages in the analysis of propositional content and the systematization of deductive inference. However, despite their considerable accomplishments, neither Leibniz nor Boole can be credited with bringing logic to its current state of maturity. They produced no inroads in the logic of relations and the use of quantifiers for the expression of generality is entirely foreign to their work. These shortcomings were addressed by later logicians working in the algebraic tradition (e.g., Pierce and Schröder), but the significance of their resolution for the development of modern formal logic and its philosophical offshoots will be better appreciated if we adopt a somewhat different

perspective on the historical interplay between logic and mathematics.

Logic and Language in Frege

For the better part of his career, the philosopher-mathematician Gottlob Frege (1848–1925) devoted his energies to establishing the 'logicist' thesis that arithmetical truth and reasoning are founded upon purely logical principles. At an early stage in his efforts, Frege realized that existing systems of logic were inadequate for carrying out the analysis of content necessary for establishing arithmetic's logical character. His *Begriffsschrift* (or 'concept notation') (1879) was intendes to address this deficiency. The logical system that Frege presented in the *Begriffsschrift* and later refined in Part I of his *Grundgesetze Der Arithmetic* (1893) constitutes the greatest single contribution in formal logic since the time of Aristotle. The most distinctive aspects of Frege's logic are (1) the use of variables and quantifiers in the expression of generality; (2) the assimilation of predicates and relational expressions to mathematical expressions for functions; (3) the incorporation of both propositional logic and the logic of relations within (second-order) quantificational logic; (4) the notion of a formal system – i.e., of a system comprising a syntactically rigid language along with explicit axioms and inference rules that together determine what is to count as a *proof* in the system.

Frege's approach to generality is based on his analysis of predication in terms of function and argument. In arithmetic, a term such as $7+5$ can be viewed dividing into function and argument in different ways. For instance, it can be treated as dividing into the function $(\ )+5$ with 7 as argument, or as dividing into the function $7+(\ )$ with 5 as argument, or as dividing into the binary function $(\ )+[\ ]$ with 7 and 5 (in that order) as arguments. Frege's approach to predication assimilates the analysis of sentences to this feature of the analysis of arithmetical expressions. For example, a simple sentence such as 'John loves Mary' can be regarded as predicating the (linguistic) function '( ) loves Mary' of the singular term 'John,' or the function 'John loves ( )' of the singular term 'Mary,' or the relational function '( ) loves [ ]' of 'John' and 'Mary' (in that order). In the *Begriffsschrift,* Frege remarked that, for simple sentences like this, the analysis into function and argument makes no difference to the 'conceptual content' that the sentence expresses. However, the *possibility* of analyzing a sentence in these ways is nevertheless crucial to logic, since only on this basis do we recognize logical relationships between generalizations and their instances. Adopting a standard arithmetical practice, Frege makes use of variables as a means of expressing generality. For example, by putting the variable 'x' in the argument-place of 'Mary' in our example, we arrive at the statement 'John loves x,' which is the *Begriffsschrift* equivalent of the colloquial generalization 'John loves all things.' The inference from this generalization to 'John loves Mary' now *requires* that we regard 'Mary' as argument to the function 'John loves ( ),' since only so is 'John loves Mary' recognizable as an *instance* of the generalization. Other function-argument analyses become salient in connection with other generalizations to which the statement relates as an instance (e.g., 'x loves Mary').

In the system of the *Begriffsschrift,* the above described use of variables suffices to express generality in a limited variety of sentential contexts. However, Frege's broader treatment of generality involves a second crucial component, namely, the use of quantifiers – i.e., the variable binding operators '$\forall x$' (read: 'Every x') and '$\exists x$' (read: 'some x') – as a means of indicating the *scope* of the generality associated with a variable. (Our discussion here prescinds from the peculiarities of Frege's now obsolete notation as well as his convention of treating existential quantification in terms of universal quantification and negation – i.e., his treatment of '$\exists x \ldots$' as '$\sim\forall x\sim \ldots$'). One of the many ways in which the use of quantifiers has proven important to logic concerns the expression of multiply general statements, for which no adequate treatment existed prior to the *Begriffsschrift.* Consider, for example, the relational generalization 'Everyone loves someone.' This statement is ambiguous between the following two readings: (1) 'There is some (at least one) person that is loved by all,' and (2) 'Every person is such as to love some (at least one) person.' The use of quantifiers resolves this ambiguity by requiring that expressions of generality in multiply general statements be ordered so as to reflect scope. The first reading of the statement is expressed by the existentially quantified sentence

$$\text{`}\exists y \forall x\ xLy\text{'}$$

where the scope of universal quantifier falls *within* that of the existential quantifier. (For convenience, we assume here that the variables 'x' and 'y' are restricted to a domain of persons.) By contrast, the second reading is given by the sentence

$$\text{`}\forall x \exists y\ xLy\text{'}$$

where the universal quantifier has wide scope with respect to the existential quantifier. Since the *Begriffsschrift*'s formation rules ensure that the scope of a quantifier will be properly reflected in

any sentence in which it occurs, an ambiguous sentence such as the one we started with cannot even be *formulated* in the language. Scope considerations apply in essentially the same way to sentential operators (e.g., the negation sign '$\sim$,' and the conditional sign '$\rightarrow$') in the logic of the *Begriffsschrift*. For instance, the ambiguity of the sentence 'Every dog is not vicious' results from the fact that, as stated, the sentence does not determine the scope of the negation sign with respect to that of the universal quantifier. On one reading, the scope of the negation sign falls within that of quantifier, i.e., '$\forall x(Dx \rightarrow \sim Vx)$,' the statement thus affirming that anything that is a dog is not vicious (or, colloquially expressed: 'No dogs are vicious'). By contrast, when the statement is read as giving wide scope to the negation sign, i.e., '$\sim\forall x(Dx \rightarrow Vx)$,' it becomes the denial of the generalization that all dogs are vicious (i.e., 'It is not the case that all dogs are vicious'). As the above examples begin to suggest, Frege's technique of ordering of operators according to scope provides the basis for his incorporation of both propositional logic and the logic of relations within quantificational logic.

Frege's philosophical interest in language extended beyond his characterization the formal mechanisms of a logically perspicuous language such as the *Begriffsschrift*. In the classic paper 'On Sense and Reference' (1892), Frege presented a framework for a general theory of meaning applicable to both natural languages and formal languages. The core of the doctrine consists in the contention that any adequate account of the meaning of a linguistic expression must recognize two distinct, but related, semantic components. First, there is the expression's *reference,* i.e., its denotative relation to a *referent* (or denoted entity). Second, there is the expression's *sense,* which Frege characterized as a particular manner in which the expression's referent is cognitively presented to the language user. Frege motivated this distinction by drawing attention to sentences in which the meaning of a singular term is apparently *not* exhausted by its correlation with a referent. For example, if the meaning of a singular term were to consist only in what it refers to, then the true, but non-trivial, identity statement 'The evening star is the morning star' could not differ in meaning from the *trivially* true identity statement 'The evening star is the evening star.' Since the latter statement results from the former by substituting co-referential singular terms, any view that equates meaning with reference will necessarily fail to register any difference in meaning between the two statements. But the two sentences clearly *do* differ in meaning, since 'The evening star is the morning star' is not a trivial identity, but an informative identity – indeed, one that expresses the content of a genuine astronomical discovery – whereas 'The evening star is the evening star' is plainly trivial. Frege accounts for this by suggesting that while 'the evening star' and 'the morning star' have a common referent, they express different senses. A language user therefore grasps the common referent differently in connection with each of the two expressions, and this in turn accounts for the difference in 'cognitive value' between the two identity statements. Frege applies the notion of sense to similar effect in addressing puzzles concerning the meaning of singular terms in so-called 'intensional contexts,' for example, belief reports.

In subsequent writings, Frege extended the sense-reference distinction beyond the category of singular terms (which, on Frege's account, refer specifically to 'objects'), to *all* categories of linguistic expression, including mondadic and polyadic predicates (which refer to 'concepts' and 'relations,' respectively), and complete sentences. In the case of sentences, Frege identified as referents the two truth-values, 'the true' and 'the false,' and he characterized these as special 'logical objects.' A sentence's sense is, by contrast, the 'thought' it expresses, where the thought is understood as a compositional product of the senses of the sentence's linguistic subcomponents. As strained as this extension of the theory may appear, particularly with respect to reference, it brings to light two important features of Frege's approach to meaning. First, it reflects his insistence that the theory of reference should comprise, *inter alia,* a theory of *semantic value* – that is, a systematic account of how the semantic values of complex expressions (which, in the case of sentences, are truth-values) are determined on the basis of the semantic values of their subordinate constituents. Second, it reflects an endeavor to integrate the theory of semantic value with a plausible general account of *linguistic understanding* (as given by the theory of sense). Seen in light of these general ambitions, Frege's theory of sense and reference proposed an agenda that any comprehensive approach to the theory of meaning must in one way or another respect – a point that is amply borne out by subsequent developments in analytic philosophy of language.

Russell: Definite Descriptions and Logical Atomism

The idea that logical analysis forms the basis of a general philosophical method is central to the philosophy of Bertrand Russell (1872–1970). It is especially prominent in the works Russell produced over the first quarter of the twentieth century. In this period, Russell developed and defended the doctrine of

'logical atomism,' which grew out of his attempt to establish a version of logicism in the philosophy of mathematics, and came to encompass a wide variety of semantic, metaphysical, and epistemological ambitions. The common thread in Russell's approach to these matters consists in his emphasis on logical analysis as a method for clarifying the ontological structure of the world and the epistemological basis of our knowledge of it. As Russell put it, "the atom I wish to arrive at is the atom of logical analysis, not physical analysis" (1918: 37). Bound up with the notion of a logical atom, understood as a basic residue of logical analysis, is the notion of logical structure itself. Our aim in this section is to illuminate Russell's conception of logical structure, or 'logical form,' as it emerges in his theory of linguistic meaning and in his broader atomism.

Russell's theory of 'definite descriptions,' first articulated in his classic paper 'On denoting' (1905), paradigmatically illustrates Russell's methodological reliance on logical analysis in addressing questions about meaning. The argument of the paper involves, among other things, the defense of a principle that Russell regarded as fundamental to the account of linguistic understanding. In *The problems of philosophy*, Russell gave the following succinct statement of the principle: "Every proposition which we can understand must be composed wholly of constituents with which we are acquainted" (1910: 32). At the time of 'On denoting,' Russell meant by a 'proposition,' roughly, the state of affairs that is expressed by an indicative sentence, whether or not that state of affairs actually obtains. A proposition's 'constituents' are the real-world entities that figure in the state of affairs (or *would* figure in it, were the state of affairs to obtain). So understood, a proposition is not a linguistic entity, even in the attenuated sense of a Fregean thought. A proposition is, rather, a structured entity that comprises various nonlinguistic components of the world. What characterizes Russell's principle of acquaintance as a principle of linguistic understanding, then, is not the linguistic *nature* of propositions, but the correlativity of propositions with the indicative sentences of a language. For Russell, understanding any such sentence requires direct experiential acquaintance with the non-linguistic constituents comprised in the proposition it expresses.

In 'On denoting' Russell addressed problems that the principle of acquaintance ostensibly confronts in connection with 'denoting phrases' – i.e., phrases of the form 'some *x*,' 'every *x*,' and especially 'the *x*' (i.e., so-called 'definite descriptions'). Consider the statement: 'The author of "On denoting" was a pacifist.' Since Russell's principle requires acquaintance with a proposition's constituents as a condition for linguistic understanding, it would seem that only those personally acquainted with the author of 'On denoting' (i.e., with Russell himself) are in a position to understand the sentence. However, this highly counterintuitive consequence only arises on the assumption that the denoting phrase 'the author of "On denoting"' functions as a genuine singular term, one that singles out Russell as a *constituent* of the corresponding proposition. Russell's account of definite descriptions challenged this assumption by arguing that the characterization of definite descriptions as singular terms arises from a mistaken account of the logical form sentences containing them. According to this mistaken analysis, the sentence 'The author of "On denoting" was a pacifist' is an instance of the simple subject-predicate form *Ps*, where *s* indicates the occurrence of a singular term and *P* the occurrence of a predicate. Russell maintained that sentences containing definite descriptions have a far richer logical structure than this account would suggest. On Russell's analysis, the statement 'The author of "On denoting" was a pacifist' is not a simple subject-predicate statement but has the form, rather, of a multiply quantified statement:

$\exists x((x$ authored 'On denoting' & $\forall y\,(y$ authored 'On denoting' $\rightarrow y = x))$ & x was a pacifist)

On this analysis, the statement says: there is an *x* such that (1) *x* authored 'On denoting,' (2) for any *y*, if *y* authored 'On denoting,' then $y = x$ (this clause serving to ensure the uniqueness implied by the use of the definite article) and (3) *x* was a pacifist. So construed, the only nonlogical components of the sentence are the descriptive predicates '( ) authored "On denoting"' and '( ) was a pacifist,' with no trace remaining of the putative singular term 'the author of "On denoting"'. Therefore, beyond an implicit understanding of the mechanisms of quantification and the logical relation of identity, acquaintance with the referents of these descriptive predicates suffices for understanding the sentence. The sentence still manages to be *about* Russell since he, and he alone, satisfies the descriptive predicates (or 'propositional functions,' in Russell's terminology) contained in the sentence. However, it no longer singles out Russell as a *constituent* of the corresponding proposition, thus dispensing with the worry that the principle of acquaintance would require personal acquaintance with Russell as a condition for understanding what the sentence means.

The theory of definite descriptions vividly conveys the sense in which, for Russell, the surface grammar of natural language is inadequate as a guide to the analysis of logical form. Indeed, Russell maintained that many of the metaphysical and epistemological perplexities of traditional philosophy were a direct

result of conflating the grammatical forms of natural language sentences with logical forms of the propositions we manage to express in natural language. In this connection, it is important to recognize that, for Russell, logical form is not a purely linguistic notion. We have already taken note of the fact that Russell's early philosophy treats propositions as structured complexes that array various non-linguistic components of reality. Though Russell ultimately abandoned his early theory of propositions, he never abandoned the view that reality itself exhibits varieties of structure to which the details of a suitably perspicuous logical language must answer. In his lectures on *The philosophy of logical atomism* (1918), this view takes the form of a doctrine of 'facts,' where facts are understood as real-world complexes of individual objects and the properties and relations predicable of them. On Russell's characterization, a fact is a kind of complex that is inherently apt to determine a corresponding indicative statement as true or false – that is, true when the statement affirms the fact, and false when it denies it. The kernel of Russell's atomism consists in the view that the content of any statement (of whatever order of complexity) is ultimately analyzable in terms of the constellation of logically primitive facts that determine the statement as true or false. Russell's inventory of such facts includes 'atomic facts,' in which properties and relations are predicated of metaphysically 'simple' entities, and 'general facts,' which are facts concerning *all* or *some* of a particular category of entity. Atomic facts correspond to the atomic sentences, and general facts to the quantified sentences, of a logically regimented language. All other sentences are 'molecular' in the sense that they are compounds built up from atomic sentences and quantified sentences by the application of logical connectives such as 'not,' 'and,' 'or,' and 'if . . . then . . . .' Though molecular sentences assert neither atomic nor general facts, their truth or falsity is nevertheless *dependent upon* such facts in the sense that a molecular sentence will be determined as true or false *as a function of* the truth or falsity of its non-molecular subsentences. For example, if '*p*' and '*q*' are atomic sentences, then the disjunction '*p* or *q*' will be true just in case one or both of '*p*' and '*q*' are true, where the truth or falsity of these subsentences is determined directly by the atomic facts to which they relate.

Russell's metaphysical view of logical form – that is, his view that logical structure is an inherent characteristic of the facts that the real world ultimately comprises – is nicely expressed in a comment from his *Introduction to mathematical philosophy.* There Russell maintains that "logic is concerned with the real world just as truly as zoology, though with its more abstract and general features" (1919: 169). At least part of Russell's motivation for this 'substantive' conception of logic consists in his abiding conviction that the structure of language (or of an ideal language, at any rate) and the structure of the world must in some way coincide if there is to be any prospect of expressing our knowledge of the world by linguistic means. The task of giving a detailed account of this community of form between language and world was one that Russell wrestled with many times over, but which he ultimately left to the talents of his most gifted student, Ludwig Wittgenstein – the second great exponent of the philosophy of logical atomism.

Wittgenstein on Logic and Language

Of the figures we are discussing, arguably Wittgenstein (1889–1951) addressed the question of the relation between logic and language most extensively. His earliest major work, the *Tractatus logic-philosophicus,* devotes much attention to this problem. It is on this early work that we will focus here. In this work he praised Russell for discovering that the apparent logical form of a proposition need not be its real logical form. He supplemented Russell's view with the claim that the real form of a proposition is a picture of a state of affairs in the world.

Propositions, according to the *Tractatus,* are pictures of facts. The structure of a proposition mirrors the structure of the fact it represents. What a fact and the proposition that describes it have in common is their form. "The picture, however, cannot represent its form of representation; it shows it forth" (2.172). Here we see the important Tractarian distinction between *saying* and *showing*. The statement 'it is now raining' *says* something about the world. The statement 'it is either the case that it is now raining or it is not the case that it is now raining' *says* nothing about the world. It does, however, *show* the logical relations between facts. If something can be shown it cannot be said (4.1212). It follows that nothing concerning the logical relations between facts can be said.

According to the *Tractatus* "the world is the totality of facts, not of things" (1.1). That is to say, the world is not completely described by a list of all the objects that it contains. Rather, a complete description of the world would consist of all true sentences. Facts can either be atomic or compound, and correspondingly there are two types of propositions. Atomic facts are the most basic type of fact, and all atomic facts are independent of one another. Likewise, any possible set of atomic propositions could be true at the same time. This does not hold generally, as p and ~p (it is not the case that p) cannot both be true at the same time. Compound propositions are built up

by *truth functions* on atomic proposition. Any operator, including the logical operators (and, or, not, . . .), that takes sentences as arguments and assigns a truth value to the compound expression based only on the truth value of the arguments, is called a truth functional operator. For instance, 'or' designates a truth function with two argument places: the truth value of the sentence 'p or q' depends only on the truth value of the sentences 'p' and 'q'. On the other hand, in the sentence 'Julius Caesar conquered Gaul before Rome fell to barbarians,' '. . .. before____' designates a function that takes sentences as arguments, but it is not truth functional since we need to know more than the truth value of the arguments to determine the truth value of the compound. Wittgenstein observed that all propositions are either atomic or built up by truth functions on atomic propositions. Because of this all propositions can be expressed as a truth function on a set of atomic propositions.

Statements such as all of those of the form 'p or ~p' are tautologies: they are true no matter what the truth value of the constituents. We can know for certain that a tautology is true, but this is only because tautologies are true independently of which atomic facts turn out to be true (and because all sentences are truth functions of atomic sentences). We cannot say that the world has a certain logical structure, this can only be shown. It is tautologies that show the logical syntax of language, but tautologies say nothing. "Logical propositions describe the scaffolding of the world, or rather they present it. They 'treat' of nothing" (6.124).

Concerning sentences of natural language, Wittgenstein thought that no serious reconstruction is necessary. "In fact, all the propositions of our everyday language, just as they stand, are in perfect logical order" (5.5563). Furthermore, Wittgenstein thought that what he says about the logical structure of language must already be known by anyone who can understand the language. "If we know on purely logical grounds that there must be elementary propositions, then everyone who understands propositions in their unanalysed form must know it" (5.5562). Remember that Wittgenstein, following Russell, distinguished between the apparent logical form of a proposition and its real logical form. The logical form of natural languages is extremely complex and shrouded in conventions. "Man possesses the capacity of constructing languages, in which every sense can be expressed, without having an idea of how and what each word mean – just as one speaks without knowing how the single sounds are produced. Colloquial language is part of the human organism and is no less complicated than it. From it it is humanly impossible to gather immediately the logic of language" (4.002).

While ordinary use of natural language is in perfect logical order, philosophy arises from the abuse of natural language. Wittgenstein thinks that philosophy is nonsense because it attempts to state what cannot be said. "Most propositions and questions, that have been written about philosophical matters, are not false, but senseless" (4.003). The view that philosophy as standardly practiced is senseless, and therefore that a radically new approach to philosophy must be developed had a profound influence on a group of philosophers who held weekly meetings in Vienna – the Vienna Circle.

Carnap and the Vienna Circle

Rudolf Carnap (1891–1970) is generally regarded as the most influential member of the Vienna circle. This group (often called the logical positivists or logical empiricists) studied Wittgenstein's *Tractatus* carefully and much of what they wrote was inspired by or was a reaction to this work. Logical positivism is often thought of as being characterized by its commitment to *verificationism*. In its strictest form, verificationism is the view that the meaning of a sentence consists in the method of its verification – that is, in the epistemic conditions under which the statement would properly be acknowledged as true. In a less strict form, it is the view that the meaning of a sentence consists of what would count as evidence for or against it. There was much debate in the circle as to what form the verificationist principle should take. There was in the circle very little objection (Gödel being the notable exception) to the thesis that there are two different kinds of statements – empirical (synthetic) and logico-mathematical (analytic) statements. Concerning empirical statements, their meaning is given by what would amount to a verification (or confirmation on a less strict view) of the statement or its negation. Concerning logico-mathematical statements, the circle was much influenced by Wittgenstein's view that tautologies are *a priori* truths – truths that are knowable independently of experience because they say nothing concerning the state of the empirical world.

What Wittgenstein counted as a logical truth (a tautology) was not sufficiently broad to include all of mathematics. Since mathematical truths are not empirical assertions, members of the Vienna circle thought they should have the same status as other logical truths. Carnap undertook to broaden the definition of logical truth so as to include all mathematical statements. To do this Carnap had to answer the question of what makes something a logical truth. Carnap's answer to this question involved the adoption of a strong form of conventionalism, which he

expressed in terms of his famous 'principle of tolerance': "In logic, there are no morals. Everyone is at liberty to build up his own logic, i.e. his own form of language, as he wishes. All that is asked of him is that, if he wishes to discuss it, he must state his methods clearly, and give syntactic rules instead of philosophical arguments" (*The logical syntax of language,* §17). This principle states that logical truth is a matter of convention. Which statements are treated as belonging to the set of analytic statements is a matter of pragmatic decision, provided that the set can be clearly defined. There is, for Carnap, no logical structure of the world that is either rightly or wrongly captured by our choice of logic. Logical relationships between sentences are a matter of stipulation on our part. However, by classifying logical statements as analytic, and therefore independent of empirical circumstances, Carnap preserves the Wittgensteinian idea that logical truths say nothing about the world. Carnap later summarized his position on logico-mathematical truth by claiming that analytic statements are true in virtue of their meaning.

Carnap's principle of tolerance was inspired by the debates concerning the foundations of mathematics in the 1920s. One party in this debate were the intuitionists, who did not believe that we have grounds to assert a mathematical sentence of the form 'p or ~p,' unless we have a proof of either p or of ~p. According to classical logic, the sentence 'p or ~p' is a tautology; it therefore stands in no need of prior justification. Intuitionists, therefore needed to abandon classical logic in favor of a logic that would not count all instances of the law of the excluded middle (p or ~p) as valid. Carnap saw both classical and intuitionistic logic as well motivated, and saw nothing that could decide between the two. He therefore saw the decision of which logic to adopt as a matter of choice.

Further developments in logic amplified the differences between Carnap and Wittgenstein. Gödel's famous incompleteness theorems made use of a technique that has since become known as Gödel numbering. By Gödel numbering we assign code numbers to expressions of the language. Through this coding technique, a language capable of expressing arithmetical properties becomes a device for discussing certain syntactic properties of any language system. Carnap saw this as a refutation of Wittgenstein's idea that the logical syntax of language is inexpressible. In fact, one of the general goals of Carnap's *The logical syntax of language* was to show that it is possible to deal in a clear systematic manner with the syntactic properties of any language. Recall that for Wittgenstein, we cannot say anything concerning the logical syntax of language.

Carnap's logical tolerance led him to assert that even statements of the form $(\exists x)Px$, which assert the existence of an object with the property P, might be true by stipulation. That we could stipulate an object into existence seemed odd to many philosophers. In order to address this worry, Carnap formulated a distinction between *internal* and *external* questions of existence. In the language system of arithmetic it is provable that $(\exists x)\ (7 < x < 9)$. Relative to this language, the question of the existence of numbers is trivial. But when someone asks whether numbers exist they do not mean to be asking the questions in such a manner that it is answerable in by appeal to the standards of proof and disproof that prevail in arithmetic. Rather, they mean to ask if the numbers really exist in some absolute sense. Carnap viewed such 'external' questions as unanswerable given that they remove the questions from a context in which there are clear standards for addressing it, without embedding it in another context where there are any such standards. But the coherence of the language system that includes, for instance, the numbers does not depend on a positive answer to the external question of the existence of numbers. In this way, not only the logical structure of the world but its ontology as well becomes a matter of convention.

Quine: the Thesis of Gradualism

W. V. O. Quine (1908–2000) began his philosophical career as a self-described disciple of Carnap's. However, from his earliest interaction with Carnap, Quine questioned Carnap's strict division between analytic and synthetic sentences. This early reaction to Carnap's work grew into a major break between the two philosophers. Recall that the analytic/synthetic distinction divides sentences (respectively) into those that concern the world and are capable of being empirically confirmed, and those that are accepted by stipulation and are true in virtue of meaning. Quine thought that this difference in kind ought to be replaced with a difference of degree. This is known as the thesis of gradualism.

For Quine our knowledge forms a structure like a web. The nodes of the web are sentences and the links between nodes are entailment relations. Only at the periphery are our decisions to accept or reject sentences directly influenced by experience. Decisions over sentences closer to the center are of an increasingly 'theoretical' character, with accepted logical and mathematical statements forming the most central class. The ordering of sentences from periphery to interior is based on how willing we would be to abandon a sentence when revising our beliefs in light of new evidence. For sentences like 'this table

is red' we can easily imagine a set of experiences that would lead us to abandon it. By contrast, it is far more difficult to imagine the experiences that would lead us to abandon '$2 + 2 = 4$.' Abandoning this statement would entail a far more radical change in our overall belief system. However, for Quine, the difference is one of degree, rather than kind. No sentence, mathematical, logical or otherwise, is ultimately immune from revision in light of experience. Physics, for instance, in departing from Euclidean geometry has abandoned sentences such as 'between any two points exactly one straight line can be drawn' once believed to be on the firmest foundation.

We have seen that, for Carnap, logico-mathematical truths are not responsible to any aspect of the world. We are perfectly free to accept any set of sentences to count as analytic. The way the world is affects only the practical utility of our choices of analytic statements; it does not affect the theoretical legitimacy of those choices. (However, Carnap is far more interested in giving reconstructions of existing notions instead of constructing arbitrary systems.) For Quine, on the other hand, logical and mathematical truths are on par with highly theoretical statements of physics. It may turn out that by abandoning classical logic or altering our mathematics we will be able to formulate more simple scientific theories. Since simplicity is one of the norms of theory choice, it may be that our best scientific theory does not conform to the laws of classical logic.

Carnap's principle of tolerance suggests that logical truths are true by virtue of the meanings assigned to the logical vocabulary. Quine rejects this view and sees logical truths as subject to the same standards of acceptance as any other scientific claim. Since there are a certain sets of experiences that would lead us to reject what we now regard as a logical truth, Quine maintained that we could no longer hold, as Wittgenstein did, that logical truths are true independently of how things happen to be in the empirical world. Logical truths therefore lose their special status and become statements on par with other scientific claims. They are true because they are part of our best description of the world.

Logical and Linguistic Notation

J Lawler, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Notation is a conventional written system for encoding a formal axiomatic system. Notation governs

- The rules for assignment of written symbols to elements of the axiomatic system
- The writing and interpretation rules for well-formed formulae in the axiomatic system
- The derived writing and interpretation rules for representing transformations of formulae, in accordance with the rules of deduction in the axiomatic system.

All formal systems impose notational conventions on the forms. Just as in natural language, to some extent such conventions are matters of style and politics, even defining group affiliation. Thus, notational conventions display sociolinguistic variation; alternate conventions are often in competing use, though there is usually substantial agreement on a 'classical' core notation taught to neophytes.

This article is about notational conventions in formal logic, which is (in the view of most mathematicians) that branch of mathematics (logicians, by contrast, tend to think of mathematics as a branch of logic; both metaphors are correct, in the appropriate formal axiomatic system) most concerned with many questions that arise in natural language, e.g., questions of meaning, syntax, predication, well formedness, and – for our purposes, the most important such – detailed, precise specification. Specification is the purpose of notation, both in mathematics and in science, but such precise conventions are unavoidably context sensitive. Thus, the use of logical notation is different in logic and in linguistics. Bochenski (1948; English translation 1960) is still the best short introduction to logical notation.

Almost all logical notation is modern, dating from the last century and a half. However, there is some prior work that deserves comment here, because logic, alone of all mathematical fields, was widely studied and significantly developed in the European Middle Ages.

The principal concern of medieval logicians was the syllogism. By the time of the Renaissance, there was an extensive and thorough account of syllogistic. One of its major achievements was the development of systematic names for the modes of the syllogism. These names (as conventionally grouped, *Barbara, Celarent, Darii, Ferio, Barbarix, Feraxo; Cesare, Festino, Camestres, Baroco, Camestrop, Cesarox; Darapti, Disamis, Datisi, Felapton, Bocardo, Ferison; Bramantip, Camenes, Dimaris, Fesapo, Fresison, Camenop*) constitute the first real notational convention in logic.

The names are mnemonic, designed to be chanted, like Pāṇini's rules. The three vowels in each name are the letters *A, E, I, O,* which mark the vertices of the Square of Opposition, indicating the proposition type (respectively, Universal Affirmative, Universal Negative, Existential Affirmative, and Existential Negative) of each of the three propositions of the syllogism. The letters *s, p, m,* and *c* also have specific meanings in these mnemonics, summarizing relevant logical properties of each type, thus serving the notational goal of detailed, precise specification. Syllogistic is largely of historical interest in modern logic, but its concerns, terminology, and notation continued to be used and understood until well into the development of modern logic.

In modern logic and mathematics, notation is a necessary part of a *calculus*, one of a number of special sets of formalized concepts and techniques for manipulating them. The metaphor refers to the origins of classical *calculation*, which was performed with pebbles (Lat *calculus*) on a counting table or *abacus*. This metaphor licenses notational practice with formal systems, which is to

- Encode: represent parts (hopefully, natural parts) of a quantity, concept, or truth with symbols, then
- Calculate: push those symbols around in conventionally accepted fashions, hoping thereby to
- Decode: find in the changed symbolic patterns representations of previously unknown quantities, concepts, or truths.

Calculi are an invention of the 17th century; the best known are Leibniz's integral calculus and Newton's differential calculus, which (together) are understood as the default meaning of *calculus* in modern English.

There are many calculi in modern mathematics, some of which exist in name only, such as Leibniz's putative *calculus ratiocinator.* In symbolic logic, which is the closest thing to what Leibniz called for, the two most important calculi, each with its own notational conventions, are Propositional Calculus and Predicate Calculus, both of which were originally intended straightforwardly (as the titles of their original publications show) as tools for the representation of human thought. Language did not enter into the picture at first, except as a transparent expression of thought.

Propositional Calculus

Symbolic logic, and its notation, originated in the works of George Boole (1815–1864), of which Boole (1854) is the best known. Boole's intention was to produce an algebraic account of propositions as combined via what we have come to call *Boolean* connectors, principally (logical) *and*, *or*, *not*, *equivalent*, and *implies*, which then achieved the dual status of both English words that are prominent in logical discussion and mathematically defined functors. Boole first made explicit the alternation between logical *and* and *or* enshrined in DeMorgan's Laws, comparing them (respectively) to multiplication and addition in algebra; thus he represented *x and y* as *xy*, whereas *x or y* was $x + y$; he used numbers throughout, using $1 - x$ to represent *not x*, for instance. This notational convention, and the system based on it, is often called *Boolean Algebra* (though technically it is a *complemented distributive lattice*, not an algebra). Boole's logic did not use quantifiers *per se*; instead, he dealt with the quantification inherent in syllogistic by using the traditional letters *A, E, I, O*.

Propositional calculus, the calculus of arbitrary whole propositions without regard to their predicates or arguments, uses two major notations. One, usually called 'Classical' or 'Standard,' exists in numerous individual variations and is usually the one taught to students; the other, called 'Polish,' 'Łukasiewicz,' or 'Prefix,' is standardized and in widespread use.

Classical notation for propositional calculus uses lowercase letters for propositions (traditionally *p, q, r, s*) and special symbols for their connectives. The two truth values of a proposition are usually either T and F, or 1 and 0. In ternary logics, T / F / # is more common than numeric codes, because arithmetic systems like 1 / 0 / −1 or 1 / ½ / 0 make implicit combinatorial claims.

The Classical special symbols for functors include those shown in Table 1.

In each case, the first symbol is the most widely accepted. In addition to functors, propositional logic also contains symbols for pragmatic connectives used in proofs, such as entailment, which usually uses a single arrow (→), and assertion, which uses a variety of symbols, including ⊢.

Table 1 Classical special symbols for functors

not p	¬p, -p, ∼p, p
p and q	p ∧ q, p • q, p & q, pq
p or q	p ∨ q
p is equivalent to q	p ⊃ q, p → q, p ⇒ q
p implies q	p ≡ q, p ↔ q, p ⇔ q

There are also parentheses, because grouping of formulae can introduce significant ambiguity, which is anathema in logic. In extended use, parentheses were found to be burdensome, because balancing them was a frequent source of avoidable error. To combat this, Whitehead and Russell in their monumental *Principia mathematica* (1910–13), developed a special parenthesis-free notation to augment their Classical formulae, based on using groups of 1,2,3, . . . dots to separate propositions. This version is rarely seen today.

Polish notation was developed and popularized by Jan Łukasiewicz (1878–1956) in the early 1920s as a by-product of his development of ternary logic, for which he also invented the truth table. In this notation, propositions are again represented by lowercase letters, but functors are uppercase letters placed immediately before their argument(s): *not p* is Np, *p and q* is Kpq, *p or q* is Apq, *p implies q* is Cpq, and *p is equivalent to q* is Epq. Because functors form valid propositions, these can be nested indefinitely without recourse to parentheses; for instance, DeMorgan's Laws, which are stated in classical notation as ¬ (p ∧ q) ≡ ¬ p ∨ ¬ q and ¬ (p ∨ q) ≡ ¬ p ∧ ¬ q, are stated in Polish notation respectively as EKNpqANpNq and EANpqKNpNq.

Because the prefixal position of the Polish functors is arbitrary, a postfixal variant, called *Reverse Polish Notation*, or RPN (linguists note that it should be called 'Japanese Notation,' because it acts like a standard SOV language), is equally valid and is widely used in computing circles, because it turns out to be ideally adapted to performing calculations using a pushdown stack. In RPN, DeMorgan's laws are stated as pNqKpNqNAE and pNqApNqNKE.

Modal Logic, an extension of propositional calculus into modality, introduces two more common notational symbols, ◇p for *p is possibly true* (in Polish notation Mp, for *Möglich*), and □p for *p is necessarily true* (Polish Lp, for *Logisch*). DeMorgan's Laws for modal logic (where □ is associated with ∧ and ◇ with ∨) can thus be stated ¬□p ≡ ◇¬p (Polish ENLpMNp) and ¬◇p ≡ □ ¬ p (Polish ENMpLNp).

Predicate Calculus

Quantified Predicate Calculus (both first- and second-order) was first axiomatized and used notationally by Gottlob Frege (1848–1925) in 1879, a quarter-century after Boole. In predicate calculus, the atomic proposition of propositional calculus is split into predicate and argument(s), allowing far more representation of actual natural language phenomena. To represent predication, Frege introduced the now-standard functional notation, widely used in

mathematics. In this notation, an atomic proposition *p* could now be seen to consist of a *predicate* (typically using uppercase letters) operating on *arguments* expressed by following parenthesized variables, in the same way as a mathematical function like $f(x) = x^2$; e.g., TALL (x) = *X is tall*, SEE (x, y) = *X sees Y*, and GIVE (x, y, z) = *X gives Y to Z*.

In particular, quantifiers were separated by Frege for the first time from their traditional Aristotelian *A, E, I, O* notation. Quantifiers in natural language are specialized words that often involve special syntax; normally they appear in construction with some noun, which they are said to *bind*. However, their syntax varies widely, and quantifier ambiguities are frequent.

Modern logic admits what McCawley (1993) calls "the logicians' favorite quantifiers": the *existential quantifier*, ∃x, pronounced 'for some *x*' or 'there exists an *x*,' and the *universal quantifier*, ∀x, pronounced 'for all/every/each *x*.' The *x*'s in each case are *dummy variables*; they do no more than indicate which variable in the proposition following is to be considered bound by the quantifier.

Quantifiers are rigidly controlled in the formulae in order to avoid ambiguity (and indeed to allow natural ambiguities to be explicated). They are placed before the formula containing the variable they bind, and their relative placement serves to denote the concept of *scope*, which is highly relevant to the three natural language elements represented in logic by operators (i.e., quantification, negation, and modality), all of which govern scope phenomena like Negative Polarity. Thus, the two ambiguous readings of *A boy beat every girl at tennis* are represented by (∃x) (∀y) BEAT (x, y) and (∀y) (∃x) BEAT (x, y).

Naturally, there are variations in quantifier notation as well: a formula like DeMorgan's Laws for quantifiers, which can be written ENPxφxSxNφx and ENSxφxPxNφx [Px is (∀*x*) and Sx is (∃*x*)] in Polish notation, comes out as ¬(∀x) φ(x) ≡ (∃x) ¬φ(x) and ¬(∃x) φ(x) ≡ (∀x) ¬φ(x) in Classical notation, which also admits a simple parenthesized variable (x) instead of (∀x), and also one with a circumflex (ŷ) instead of (∃y), in the appropriate position. The use of parentheses, colons, brackets, and other punctuation with quantifiers is inconsistent and follows individual style, which is usually oriented toward scope delimitation.

Logical Consequence

P Blanchette, University of Notre Dame, Notre Dame, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

Fundamentals

Logical consequence is the relation that holds between the premises and conclusion of an argument when the conclusion *follows from* the premises, and does so for purely logical reasons. When a conclusion is a logical consequence of premises, the truth of those premises suffices to guarantee the truth of the conclusion. To clarify, we'll look at some examples.

When we reason that

(A1) Socrates is mortal

follows from

(A2) Socrates is human

and

(A3) All humans are mortal,

we need not appeal to any known facts about Socrates, about humanity, or about mortality. These specifics are irrelevant to the fact that (A1) follows from (A2) and (A3), which shows that the sense of 'following-from' involved here is the purely logical

mathematics. In this notation, an atomic proposition *p* could now be seen to consist of a *predicate* (typically using uppercase letters) operating on *arguments* expressed by following parenthesized variables, in the same way as a mathematical function like $f(x) = x^2$; e.g., TALL (x) = *X is tall*, SEE (x, y) = *X sees Y*, and GIVE (x, y, z) = *X gives Y to Z*.

In particular, quantifiers were separated by Frege for the first time from their traditional Aristotelian *A, E, I, O* notation. Quantifiers in natural language are specialized words that often involve special syntax; normally they appear in construction with some noun, which they are said to *bind*. However, their syntax varies widely, and quantifier ambiguities are frequent.

Modern logic admits what McCawley (1993) calls "the logicians' favorite quantifiers": the *existential quantifier*, ∃x, pronounced 'for some *x*' or 'there exists an *x*,' and the *universal quantifier*, ∀x, pronounced 'for all/every/each *x*.' The *x*'s in each case are *dummy variables*; they do no more than indicate which variable in the proposition following is to be considered bound by the quantifier.

Quantifiers are rigidly controlled in the formulae in order to avoid ambiguity (and indeed to allow natural ambiguities to be explicated). They are placed before the formula containing the variable they bind, and their relative placement serves to denote the concept of *scope*, which is highly relevant to the three natural language elements represented in logic by operators (i.e., quantification, negation, and modality), all of which govern scope phenomena like Negative Polarity. Thus, the two ambiguous readings of *A boy beat every girl at tennis* are represented by (∃x) (∀y) BEAT (x, y) and (∀y) (∃x) BEAT (x, y).

Naturally, there are variations in quantifier notation as well: a formula like DeMorgan's Laws for quantifiers, which can be written ENPxφxSxNφx and ENSxφxPxNφx [Px is (∀*x*) and Sx is (∃*x*)] in Polish notation, comes out as ¬(∀x) φ(x) ≡ (∃x) ¬φ(x) and ¬(∃x) φ(x) ≡ (∀x) ¬φ(x) in Classical notation, which also admits a simple parenthesized variable (x) instead of (∀x), and also one with a circumflex (ŷ) instead of (∃y), in the appropriate position. The use of parentheses, colons, brackets, and other punctuation with quantifiers is inconsistent and follows individual style, which is usually oriented toward scope delimitation.

Logical Consequence

P Blanchette, University of Notre Dame, Notre Dame, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

Fundamentals

Logical consequence is the relation that holds between the premises and conclusion of an argument when the conclusion *follows from* the premises, and does so for purely logical reasons. When a conclusion is a logical consequence of premises, the truth of those premises suffices to guarantee the truth of the conclusion. To clarify, we'll look at some examples.

When we reason that

(A1) Socrates is mortal

follows from

(A2) Socrates is human

and

(A3) All humans are mortal,

we need not appeal to any known facts about Socrates, about humanity, or about mortality. These specifics are irrelevant to the fact that (A1) follows from (A2) and (A3), which shows that the sense of 'following-from' involved here is the purely logical

sense. That is, (A1) is a *logical* consequence of (A2) and (A3).

By contrast, when we reason that

(B1) There are mammals in the ocean

follows from

(B2) There are dolphins in the ocean

we must appeal to facts peculiar to the nature of mammals and of dolphins. We appeal, specifically, to the fact that dolphins are mammals. In this case, although there is a sense in which (B1) 'follows from' (B2), (B1) does not follow *logically* from (B2). It follows, one might say, *biologically*, because an appeal to biological facts is needed to get from (B2) to (B1). Nevertheless, the fact that (B1) follows in this extra-logical way from (B2) is because of the relation of logical consequence. Specifically, it is because of the fact that (B1) is a logical consequence of (B2) together with

(B3) All dolphins are mammals.

That (B1) is a *logical* consequence of (B2) and (B3) can be seen by noting that it follows from them independently of the specific nature of the objects, properties, and relations mentioned in these statements.

In general, all cases of 'following from' are due, in this way, to the relation of logical consequence. If a conclusion follows from some collection of premises, this is because that conclusion is a *logical* consequence of the premises, together perhaps with various ancillary claims that are presupposed in the given context.

Logical consequence is therefore a ubiquitous relation: all of our reasoning turns on recognizing (or attempting to recognize) relations of logical consequence, and virtually all of the important connections between theories, claims, predictions, and so on, are in large part due to logical consequence. Furthermore, whenever we say that a given argument is *valid* or that it is *invalid*, or that a particular set of claims is *consistent* or *inconsistent*, we are employing the notion of logical consequence: a valid argument is one the conclusion of which is a logical consequence of its premises, whereas a consistent set of claims is a collection that has no contradiction as a logical consequence. Because the central logical notions of validity, consistency, etc., are definable in terms of logical consequence, the investigation of the nature of logical consequence is at the same time the investigation of the nature of the logical properties and relations in general.

The Formal Study of Logical Consequence

The modern investigation of logical consequence is closely connected to the discipline of *formal logic*. Formal logic is the study of formal (i.e., syntactically specified) languages, and of various philosophically and mathematically significant properties and relations definable in terms of such languages. Of particular significance for the study of logical consequence are two kinds of relations definable on the formulas of a formal language, the relations of *proof-theoretic consequence* and of *model-theoretic consequence*.

Given a formal language, a relation of proof-theoretic consequence is defined via the rigid specification of those sequences of formulas that are to count as *proofs*. Typically, the specification is given by designating specific formulas as *axioms*, and designating some *rules of inference* by means of which formulas are provable one from another. Both axioms and rules of inference are specified entirely syntactically. A proof is then a series of formulas each of which is either taken as premise, or is an axiom, or is obtained by previous formulas in the series via a rule of inference. A formula φ is a proof-theoretic consequence of a set Σ of formulas if and only if there is a proof the premises of which are among the members of Σ, and the conclusion of which is φ.

Model-theoretic consequence, by contrast, is defined in terms of a range of *interpretations* (or *models*) of the formal language in question. While the vocabulary of the language is divided into the 'logical' terms (typically, analogues of the English-language 'and,' 'or,' 'not,' 'if. . .then,' and 'for all'), the meaning of which is taken as unchanging, and the 'non-logical' terms (typically analogues of natural-language predicates and singular terms), an *interpretation* is an assignment of objects and sets of objects to the non-logical terms. In the standard case, the formulas are taken to have a truth-value (i.e., to be either true or false) on each such interpretation. A formula φ is then a model-theoretic consequence of a set Σ of formulas if and only if there is no interpretation on which each member of Σ is true while φ is false.

The connection between these defined relations and logical consequence arises when the formulas in question are taken to stand as representatives of natural-language sentences or the claims they express. Given such a representation-relationship, the relations of proof-theoretic and of model-theoretic consequence are typically designed so as to mirror, to some extent, the relation of logical consequence. Thus, the idea behind a standard design of a relation of proof-theoretic consequence is that it only count as axioms those formulas representing 'logical truths' (e.g., 'Either 5 is even or 5 is not even'), and that its rules of inference similarly mirror logical principles. In such a case, a formula φ will be a proof-theoretic

consequence of a set Σ of formulas only if the kind of ordinary sentence represented by φ is indeed a logical consequence of the ordinary sentences represented by the members of Σ. This does not ensure that the relation of proof-theoretic consequence exhausts the relation of logical consequence, for two reasons: first of all, the formal language in question may not contain representatives of all ordinary sentences; second, the proof system may not be rich enough to reflect all of the instances of logical consequence amongst even those ordinary sentences that are represented in the language. The system of proof-theoretic consequence will, however, have the virtue of being well defined and tractable. Similar remarks apply to the relation of model-theoretic consequence: in a well-designed formal language, the relation of model-theoretic consequence will mirror, in important ways, the relation of logical consequence. The intention in designing such a system is, typically, that φ will be a model-theoretic consequence of Σ if and only if the kind of ordinary sentence represented by φ is a logical consequence of those represented by the members of Σ.

Given a particular language together with its proof-theoretic and model-theoretic consequence relations, the question arises whether those relations are co-extensive: whether, that is, φ is a proof-theoretic consequence of Σ if and only if φ is a model-theoretic consequence of Σ. In some cases, the answer is 'yes,' and, in some, 'no.' Each half of the inclusion is a separate, significant issue: when every proof-theoretic consequence of each set of formulas is also a model-theoretic consequence of that set, the system is said to be *sound*, and when every model-theoretic consequence of each set of formulas is also a proof-theoretic consequence of that set, the system is said to be *complete*. The soundness of a system is typically a straightforward matter, following immediately from the design of the proof-theoretic system; completeness is typically a considerably more significant issue. The most-important system of logic, that of classical first-order logic, was proven by Kurt Gödel in 1930 to be complete; this is the celebrated 'completeness theorem for first-order logic.' First-order logic is, in various ways, the 'strongest' complete system (see Enderton, 1972).

Formal systems, i.e., formal languages together with proof-theoretic or model-theoretic consequence relations, differ from each other in a number of ways. Most important for the purposes of the study of logical consequence are the following two differences: (1) proof-theoretic relations differ over the axioms and rules of inference they include, and hence over the instances of logical consequence that they represent. Some such differences are just because the languages of some such systems are expressively weaker than others, so that principles contained in one simply cannot be expressed in the other. More interesting are differences motivated by differing views of logical consequence itself. Thus, for example 'classical' logic differs from intuitionist logic in including the principle of *excluded middle*, the principle guaranteeing the truth of all statements of the form *p-or-not-p*. As the proponent of intuitionist logic sees it, this principle is not universally accurate, and hence should not be included in a system of logic. (2) Model-theoretic relations differ in a number of small ways, including the specifics of the definition of *interpretation*, and of the definition of truth-on-an-interpretation. More important, the model-theoretic consequence relations for different systems differ when the formal languages in question are importantly structurally different. Thus, for example, standard *second-order logic* has a richer model-theoretic consequence relation than does first-order logic, and there are natural-language arguments whose second-order representation yields a conclusion that is a model-theoretic consequence of its premises, but whose first-order representation does not (see van Dalen, 2001; Shapiro, 1991).

The question of the extent to which each such system gives an accurate characterization of logical consequence is of central philosophical concern. With respect to the relations of proof-theoretic consequence, debate turns on the accuracy of specific axioms and rules of inference. With respect to relations of model-theoretic consequence, the significant debate is rather over the question of the extent to which model-theoretic consequence relations in general (or, perhaps, that relation as applied to classical first-order logic) offer an *analysis* of the ordinary, non-formal relation of logical consequence. If logical consequence is in some sense 'essentially' the relation of truth-preservation across interpretations, then model-theoretic consequence has a privileged position as simply a tidied-up version of the core relation of logical consequence. If, by contrast, the relation of truth-preservation across interpretations is simply another sometimes-accurate, sometimes-inaccurate means of representing the extension of the relation of logical consequence, then model-theoretic consequence has no immediate claim to accuracy (see Etchemendy, 1990).

General Philosophical Concerns

In addition to questions surrounding its appropriate formal representation, the investigation of logical consequence includes questions concerning the nature of the relation itself.

One important cluster of such questions concerns the relata of the relation. Here we want to know whether the items between which logical consequence holds are, say, the *sentences* of ordinary language, or the non-linguistic *propositions* expressed by such sentences, or something else altogether. Although logical consequence is perhaps most straightforwardly viewed as a relation between sentences, one reason to reject this idea is that sentences, at least when thought of as syntactic entities (strings of letters and spaces), seem the wrong kinds of things to bear that relation to one another. Because any given sentence so understood could, under different circumstances, have had a quite different meaning, and would thereby have borne different logical relationships to other sentences, it is arguable that the sentence itself is not the primary bearer of this relation but is, rather, just a means of expression of the primary bearer. This line of reasoning motivates the view of non-linguistic propositions, the kinds of things expressed by (utterances of) fully interpreted sentences, as the relata of logical consequence. The central reason for rejecting *this* proposal, though, is skepticism about the existence of such things as nonlinguistic propositions. A third option is to take the relata of the logical consequence relation to be sentences-in-use, essentially pairs of sentences and meaning-conferring practices (see Cartwright, 1987; Strawson, 1957; Quine, 1970).

The second, related collection of questions concerning logical consequence arises from the inquiry into what *makes* one thing a logical consequence of others. Here, we are looking for an explanation or an analysis of logical consequence in terms of other, more well-understood notions. One potential answer is that logical consequence is to be explained in terms of the meanings of various specific parts of our vocabulary, specifically in terms of the meanings of the 'logical' words and phrases (see above). A second, not necessarily competing, account is that logical consequence is because of the *form*, or overall grammatical structure, of the sentences and arguments in question. A third type of answer, mentioned above, is that logical consequence is best explained in terms of model-theoretic consequence. Various of the accounts of logical consequence have been criticized on grounds of circularity: to say that φ's being a logical consequence of Σ is *because of* some other relation between φ and Σ is, arguably, to say that the claim that φ is a logical consequence of Σ is itself a *logical consequence* of the purported explanans. If this charge of circularity is accurate, it is arguable that all such explanations of the nature of logical consequence will be found to be circular, with the result that this relation must be taken to be 'primitive,' not capable of reduction to anything else. Part of the debate here will turn on what one takes the nature of explanation to be, and on whether explanation requires reduction (see Quine, 1936).

In short: although it generally is agreed that some claims are logical consequences of others, there is scope for important disagreement about (a) which specific claims are in fact logical consequences of which others, (b) how to construe the notion of 'claim' involved here, and (c) how to give a correct account of the nature of the relation of logical consequence. Because of the connections between these issues and general positions in the philosophy of logic, philosophy of mathematics, and philosophy of language, one's preferred answers to the questions noted here will turn in large part on one's position with respect to a host of surrounding topics.

Logical Form in Linguistics

D Blair, University of Western Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

To describe the logical form of some claim is to describe its logically significant properties and structure, showing its connection to other claims via what it entails and what it entails it. Given the variety of claims that philosophers have taken in an interest in, it is not surprising that there are a large number of theories of logical form. But even if there is no shortage of theories aiming at the logical form of, e.g., propositional attitude sentences or counterfactual conditionals, surprisingly little attention has been given to the prior question of **what** logical form is to begin with. Just as importantly, it is not clear what it is that is supposed to **have** a logical form in the first instance. Is it, for example, a linguistic object like a sentence, or the utterance of a sentence, or something different from both of these, such as the proposition expressed by an utterance of a sentence?

The presence of logic within the notion of logical form may make one suspicious of paying too much attention to the details of natural language. Other kinds of items seem better suited to having logical forms. For example, propositions have whatever truth conditions they have essentially, whereas sentences do not: 'snow is white' might have meant that most colorless beverages lack sodium. Further, it is a notorious fact about natural language that it contains a good deal of vagueness and context sensitivity that is hard to capture within a theory of inference. Facts like these have made philosophers wary of placing too much emphasis on natural language sentences. At the very least, one would want to purge natural language of its logically problematic features before building upon it a theory of logical form. This was precisely the reaction of Frege (1952) and Russell (1919) to the defects of natural language. For them, one needed to formulate an ideal language free from the flaws of natural language in order to spell out the content of various claims. Only then could one think about constructing theories of logical form. Frege's *Begriffschrift* formulated an ideal language in which to conduct arithmetic and overcame some of the difficulties of explaining inferences involving multiple quantifiers that beset earlier logical theories.

But even if having a logically perspicuous representation of the propositional content of an assertion makes it easier to assess how well a theory accords with what is said about, e.g., the good or the propositional attitudes, there are serious questions concerning how such representations are related to the grammatical properties of a sentence. In the hands of Frege and Russell, one simply translated, as best one could, from natural language into an ideal language. These languages were specifically designed to expedite inference, and so no question arises about their logical forms. But until the last few decades, the kinds of structures required for the purposes of detailing the inferential properties of natural language sentences were thought to be quite remote from anything one might call 'the grammar' of a language. Indeed, one way of **motivating** talk of logical form was by showing the deficiencies of theories of meaning built upon generalizations of apparent grammatical form and function.

A number of developments in the 1960s and 1970s changed this picture. A growing number of philosophers became intrigued with the idea of constructing theories of meaning for natural languages directly. The idea that such a theory could be done **systematically** stems in large part from the work of Noam Chomsky in the 1950s and 1960s, showing how rigorous theories of grammatical structure were possible. In light of the success of Chomsky's program, it was natural to wonder whether a semantic theory along the lines of his work in syntax could be constructed. The classic picture of the grammatical structure of a sentence involves a series of levels of representation, the most well known of which is the so-called 'T-model.' In this model, there are four 'levels of representation': D-structure, S-structure, LF, and then PF, or the phonological form of a sentence. Since the last item is a representation of a sentence's phonological properties, I leave it aside. Each level is related to the one before via the application of a rule or set of rules. The conception of rules has changed over the years, but the underlying idea is that syntactic structure of a sentence is built up, step by step, through a series of representations, each

Logical Form in Linguistics

To describe the logical form of some claim is to describe its logically significant properties and structure, showing its connection to other claims via what it entails and what it entails it. Given the variety of claims that philosophers have taken in an interest in, it is not surprising that there are a large number of theories of logical form. But even if there is no shortage of theories aiming at the logical form of, e.g., propositional attitude sentences or counterfactual conditionals, surprisingly little attention has been given to the prior question of **what** logical form is to begin with. Just as importantly, it is not clear what it is that is supposed to **have** a logical form in the first instance. Is it, for example, a linguistic object like a sentence, or the utterance of a sentence, or something different from both of these, such as the proposition expressed by an utterance of a sentence?

The presence of logic within the notion of logical form may make one suspicious of paying too much attention to the details of natural language. Other kinds of items seem better suited to having logical forms. For example, propositions have whatever truth conditions they have essentially, whereas sentences do not: 'snow is white' might have meant that most colorless beverages lack sodium. Further, it is a notorious fact about natural language that it contains a good deal of vagueness and context sensitivity that is hard to capture within a theory of inference. Facts like these have made philosophers wary of placing too much emphasis on natural language sentences. At the very least, one would want to purge natural language of its logically problematic features before building upon it a theory of logical form. This was precisely the reaction of Frege (1952) and Russell (1919) to the defects of natural language. For them, one needed to formulate an ideal language free from the flaws of natural language in order to spell out the content of various claims. Only then could one think about constructing theories of logical form. Frege's *Begriffschrift* formulated an ideal language in which to conduct arithmetic and overcame some of the difficulties of explaining inferences involving multiple quantifiers that beset earlier logical theories.

But even if having a logically perspicuous representation of the propositional content of an assertion makes it easier to assess how well a theory accords with what is said about, e.g., the good or the propositional attitudes, there are serious questions concerning how such representations are related to the grammatical properties of a sentence. In the hands of Frege and Russell, one simply translated, as best one could, from natural language into an ideal language. These languages were specifically designed to expedite inference, and so no question arises about their logical forms. But until the last few decades, the kinds of structures required for the purposes of detailing the inferential properties of natural language sentences were thought to be quite remote from anything one might call 'the grammar' of a language. Indeed, one way of **motivating** talk of logical form was by showing the deficiencies of theories of meaning built upon generalizations of apparent grammatical form and function.

A number of developments in the 1960s and 1970s changed this picture. A growing number of philosophers became intrigued with the idea of constructing theories of meaning for natural languages directly. The idea that such a theory could be done **systematically** stems in large part from the work of Noam Chomsky in the 1950s and 1960s, showing how rigorous theories of grammatical structure were possible. In light of the success of Chomsky's program, it was natural to wonder whether a semantic theory along the lines of his work in syntax could be constructed. The classic picture of the grammatical structure of a sentence involves a series of levels of representation, the most well known of which is the so-called 'T-model.' In this model, there are four 'levels of representation': D-structure, S-structure, LF, and then PF, or the phonological form of a sentence. Since the last item is a representation of a sentence's phonological properties, I leave it aside. Each level is related to the one before via the application of a rule or set of rules. The conception of rules has changed over the years, but the underlying idea is that syntactic structure of a sentence is built up, step by step, through a series of representations, each

having its own properties. Diagrammatically, what we have is the following:

The 'S-structure' or surface structure of a sentence is what corresponds, nearly enough, to the order of expressions as heard or written. 'LF' or logical form is a syntactic representation that is derived from the S-structure via a set of transformations, just as S-structures were derived from D-structures via transformations.

Since only one level of representation seems to correspond to the overt form of a sentence, it follows that a good deal of syntactic structure remains hidden. The idea that unpronounced structure can be given a grammatical motivation is compelling. Consider the following pair of sentences:

(1) John kissed Mary

(2) Who did John kiss

The leftmost WH-phrase in (2) is intuitively related to the position of 'Mary' in (1). The grammar of English disguises this fact by requiring that unstressed WH-phrases in sentences like (2) be fronted. Were English different in this regard, the parallel would be more obvious. Interestingly, a good many languages allow for just this possibility while others require all WH-phrases to be placed at the left- periphery of a sentence. A more perspicuous representation of English would abstract from these kinds of provincial eccentricities of surface form and expose, via a logically perspicuous notation, just these parallels.

There is evidence that the grammatical structure of sentences like these in different languages is abstractly identical, i.e., that all WH-phrases are located at the edge of a clause at some level of representation. In some languages, like Russian, this is overtly true, even when there are several WH phrases in the clause. In other cases, like Chinese, there is little or no movement to the edge of the clausal periphery (see Huang, 1982). The difference between the overt forms of WH-questions then doesn't disguise just the logical or semantic structure of a sentence; it hides the grammatical structure as well. A more articulated version of (2) shows this abstract structure:

(3) Who did John kiss *t*

The key idea is that movement of a WH-phrase may occur overtly, as in English, or 'covertly,' as in some cases of French. When the WH-phrase does move, however, what we end up with is (3) The movement of the WH-phrase to its position at the left edge of the clause leaves a record in the form of a 'trace,' notated above as 't.'

Structures like (3) resemble, in a rather striking way, the kinds of representations that one finds within first-order logic, in particular with respect to the relationship between a quantificational expression and a variable that it binds. Let's look at this in more detail. It is now commonplace to use examples of scope ambiguities as evidence for the ambiguity of sentences, one to be sorted out in a semantic theory. Thus, a sentence like (4) is ambiguous depending upon whether or not one takes the quantificational phrase 'every boy' to have scope over the subject quantificational phrase 'some girl' or vice versa, i.e., (5a/b):

(4) Some girl danced with every boy

(5a) $\exists x$: girl(x) [$\forall y$: boy(y) [danced(x,y)]]
(5b) $\forall y$: boy(y) [$\exists$: girl (x) [danced (x,y)]]

The usual way of describing this difference is to say that in (5a), 'some girl' has scope over 'every boy,' while in (5b), the opposite relation holds. The scope of the quantifiers is determined by looking at the material appearing to its right, i.e., the closest formula that does not contain the expression within the first order translation.

It turns out that one can define the relevant relation in syntactic terms as well, using the properties of phrase structure. To see this, consider the core syntactic relation of c-command.

An expression α c-commands an expression β if and only if the first branching node dominating α dominates β and neither α nor β dominates the other.

What is important is that one can use this definition to say something about quantificational scope. Suppose we take quantificational expressions to move to positions from which they c-command their original position:

$[_{ZP}$ XP $[_{ZP}$ ... [... [...t_i ...]..

In this case, XP c-commands ZP and everything that is contained in the latter, including the trace of XP. Strikingly, when we look at what the structure of 1 is when this structure is explicit, we see the kind of structure required for the definition of scope:

(6) $[_S\ [_{QP}$ Some girl$]_2\ [_S\ [_{QP}$ Every boy$]_1$
$[_S\ t_2\ [_{VP}$ danced t_1]]]]

For the reading of (4) where the scopes of the quantificational NPs are inverted relative to their surface order, 'every boy' is adjoined to a position from which it c-commands both ZP and the position to which 'some girl' has been adjoined:

(7) $[_S\ [_{QP}$ Every boy$]_1\ [_S\ [_{QP}$ Some girl$]_2\ [_S\ t_2\ [_{VP}$ danced t_1 $]]]]$

Both of these movements can be given more detailed defense; see May (1977). The structures that seem to be needed for semantics and that philosophers have thought were disguised by ordinary grammar really are hidden, although not quite in the way they thought. What is hidden is more syntactic structure.

Of course, 'LF' is a *syntactic* level of representation and is not a semantic representation. This is not to suggest, however, that no gain has been made within theorizing about natural language by incorporating the LF hypothesis. For one could hold that the grammatical structures that are interpreted by the semantic theory are just those provided by a theory of grammar incorporating the LF hypothesis. There is no need to first regiment the formal structures of sentences into something to which semantic rules could then apply. What one finds in the idea of LF is the idea that natural languages already have enough structure to supply a lot of what is needed for the purposes of semantics.

Further developments within syntactic theory have made the concept of logical form more prominent. Thus, Chomsky (1995) and others have proposed that the **only** level of grammatical representation is LF, although the role of LF is likely to change, just as it has in the past (see, e.g., Lasnik, 2001). Even so, it is apparent that progress has been made in joining together two bodies of thinking about language, one rooted in traditional philosophical problems about the representation of logic and inference and the other in more recent developments coming from linguistics.

There are limits, however, to how much philosophical work a linguistic-based approach to logical form can do. Recall that one of the problems that has made many philosophers wary of paying too much attention to natural language concerned such things as the context sensitivity of certain aspects of natural language sentences. It is an open question just how to treat different kinds of context sensitivity within natural language, and whether revisions are needed to our conception of logical form in natural language in order to accommodate it. It is also true that a good number of philosophical projects targeting logical form are usually concerned with the conceptual analysis of certain notions, e.g., moral goodness, knowledge, etc. Indeed, one of the traditional roles of logical form within philosophy is to serve as scaffolding for just these sorts of projects. Doubts about the viability of conceptual analysis to one side, this is what has given weight to the claim that 'ordinary language' disguises the logically significant structure of our concepts. But if this is the role that logical form must play if it is to have a role within philosophy, then it is unclear whether the linguistic conception of logical form can wholly supplant the traditional view. The linguistic conception of logical form seemingly has little to do with the conceptual analysis. And unless conceptual analysis takes the form of a grammatical analysis, it is unlikely that one can substitute grammatical analysis for the description of the logically significant aspects of our concepts.

This is not to deny that a linguistics-based conception of logical form is an important, maybe even essential part of understanding how to think about some aspects of logic and meaning. This is particularly clear with respect to the study of quantification. But there are many questions about the nature of logical form that need to be resolved before particular view can be judged to be the most viable.

Logophoric Pronouns

M von Roncador, Bayreuth University, Bayreuth, Germany

© 2006 Elsevier Ltd. All rights reserved.

Reported discourse can be seen as a procedure of integrating a secondary text into a primary text. Traditionally, two integration strategies are distinguished: direct discourse, reproducing or pretending to reproduce another text without adjusting its orientation to the primary text and speaker (*John said, "You can't stop me"*), and indirect discourse, in which the secondary text is maximally adjusted to the primary speaker's orientation (*John affirmed that I/you/she/he could not stop him*). It should be noted that the reference of the subject of the secondary clause, the reported addressee, cannot be determined in the direct discourse example, whereas in the indirect discourse example, the third-person object pronoun may be coreferring to *John* or not. Over the last decades, attention has shifted to intermediate strategies of adjustment within reported discourse (cf. Roncador, 1988), one of which is the phenomenon of logophoricity, so named by Hagège (1974). Crosslinguistically, logophoric marking may be combined with direct discourse, as well as with indirect discourse orientation (see below). A logophoric marking device or logophor in the secondary text refers obligatorily to the reported speaker defined in the primary text. Instances with logophoric marking devices can thus be unambiguous where the English translation into indirect discourse is not:

Lobiri (Central Gur)

(1a) ʔá$_i$ sóré !ʔɔ́-!ná$_i$ ʔíné
he *say* *LOG-FUT* *come*
'he$_i$ said he$_i$ would come'

(1b) ʔá$_i$ sóré !ʔá-ná$_j$!ʔíné
he *say* *3SG-FUT* *come*
'he$_i$ said he$_j$ would come'

Major questions concerning logophoricity are: (1) How is logophoricity expressed and what are its properties? (2) What is the status of logophorically marked reported discourse? and (3) What is the origin of logophoric marking and why are its most typical occurrences found in the savannah belt south of the Sahara?

Forms and Properties of Logophoric Marking

Logophoricity is typically expressed by a special pronominal form marking coreference with a subject of a speech act verb as in (1a), whereas the use of the 'normal' third person singular subject form (1b) will indicate disjoint reference (that someone else will come). There are exceptions in that logophoric marking may be expressed by a verbal suffix, possibly derived form a pronominal form, as is the case in Gokana (Hyman and Comrie, 1981); Curnow (2002) counts this as one case of his category of verbal logophoricity.

Typological properties of logophoric marking have been formulated by, amongst others, Hyman and Comrie (1981), Roncador (1992), and Culy (1994). The following conventions and abbreviations will be used here: T_0 will denote the primary text and S_0 the primary speaker; t_l the secondary text, S_l the trigger of logophoric marking (in the most typical cases the reported speaker); LOG the logophorically marked participant in t_l. The setting permitting logophoric marking (in languages with logophors) is called 'logophoric context'.

Binding

Logophors in t_l obligatorily express coreference with a participant of the primary text T_0. There exist different interpretations concerning the properties of 'normal' anaphoric devices in t_l. In most cases the absence of logophoric marking in logophoric contexts will express disjoint reference to S_l. Some authors claim that coreference of the 'normal' pronoun to S_l may be possible, but with the sense that it is the point of view of S_0 which is expressed in t_l, whereas the presence of the LOG indicates the point of view of S_l (for discussion, see Roncador 1988: 289–295).

Logophoric Pronouns

M von Roncador, Bayreuth University, Bayreuth, Germany

© 2006 Elsevier Ltd. All rights reserved.

Reported discourse can be seen as a procedure of integrating a secondary text into a primary text. Traditionally, two integration strategies are distinguished: direct discourse, reproducing or pretending to reproduce another text without adjusting its orientation to the primary text and speaker (*John said, "You can't stop me"*), and indirect discourse, in which the secondary text is maximally adjusted to the primary speaker's orientation (*John affirmed that I/you/she/he could not stop him*). It should be noted that the reference of the subject of the secondary clause, the reported addressee, cannot be determined in the direct discourse example, whereas in the indirect discourse example, the third-person object pronoun may be coreferring to *John* or not. Over the last decades, attention has shifted to intermediate strategies of adjustment within reported discourse (cf. Roncador, 1988), one of which is the phenomenon of logophoricity, so named by Hagège (1974). Crosslinguistically, logophoric marking may be combined with direct discourse, as well as with indirect discourse orientation (see below). A logophoric marking device or logophor in the secondary text refers obligatorily to the reported speaker defined in the primary text. Instances with logophoric marking devices can thus be unambiguous where the English translation into indirect discourse is not:

Lobiri (Central Gur)

(1a) ʔá$_i$ sóré !ʔɔ́-!ná$_i$ ʔíné
he *say* *LOG-FUT* *come*
'he$_i$ said he$_i$ would come'

(1b) ʔá$_i$ sóré !ʔá-ná$_j$!ʔíné
he *say* *3SG-FUT* *come*
'he$_i$ said he$_j$ would come'

Major questions concerning logophoricity are: (1) How is logophoricity expressed and what are its properties? (2) What is the status of logophorically marked reported discourse? and (3) What is the origin of logophoric marking and why are its most typical occurrences found in the savannah belt south of the Sahara?

Forms and Properties of Logophoric Marking

Logophoricity is typically expressed by a special pronominal form marking coreference with a subject of a speech act verb as in (1a), whereas the use of the 'normal' third person singular subject form (1b) will indicate disjoint reference (that someone else will come). There are exceptions in that logophoric marking may be expressed by a verbal suffix, possibly derived form a pronominal form, as is the case in Gokana (Hyman and Comrie, 1981); Curnow (2002) counts this as one case of his category of verbal logophoricity.

Typological properties of logophoric marking have been formulated by, amongst others, Hyman and Comrie (1981), Roncador (1992), and Culy (1994). The following conventions and abbreviations will be used here: T_0 will denote the primary text and S_0 the primary speaker; t_l the secondary text, S_l the trigger of logophoric marking (in the most typical cases the reported speaker); LOG the logophorically marked participant in t_l. The setting permitting logophoric marking (in languages with logophors) is called 'logophoric context'.

Binding

Logophors in t_l obligatorily express coreference with a participant of the primary text T_0. There exist different interpretations concerning the properties of 'normal' anaphoric devices in t_l. In most cases the absence of logophoric marking in logophoric contexts will express disjoint reference to S_l. Some authors claim that coreference of the 'normal' pronoun to S_l may be possible, but with the sense that it is the point of view of S_0 which is expressed in t_l, whereas the presence of the LOG indicates the point of view of S_l (for discussion, see Roncador 1988: 289–295).

It has been noted frequently that in most languages with logophoric marking, the binding domain cannot be defined syntactically (see Roncador, 2002 for textually bound logophors). Nevertheless, in some languages logophors may be syntactically bound (see Koopman and Sportiche, 1989 for a generative approach). In any case, logophoric marking will take place outside of S_0, thus distinguishing it from long-distance anaphora and reflexives.

Properties of T_0 and S_l

T_0 may introduce words, ideas, or emotional attitudes; see Culy (1994, 2002) for a scalar ranking of predicates introducing (triggering) LOG, including verbs of saying at the top and predicates expressing experiences or finality at the bottom. If there is a reported speaker in T_0, then he will be the source S_l, otherwise another subject of consciousness may also be S_l. This correlates with well-known implicata in that the agent in T_0 is more likely to trigger LOG than the experiencer (and consequently the patient), and a subject is more likely to trigger LOG than an (indirect) object, etc. For a number of Chadic languages, Frajzyngier (1985) reported the marking of not only the reported speaker in t_l, but also the reported addressee by a special form, sometimes called 'addressee pronoun/logophor'.

S_1 is also subject to a hierarchy of person and number in that a third person is more likely to trigger logophoric marking than a second and a first person, singular more likely than plural. In fact, different logophoric marking for all persons seems not to be attested, but syncretism of person is reported, e.g., in Gokana (Hyman and Comrie, 1981), though it is unusual for a first person S_1. Quite frequently, there is syncretism of third and second person in logophoric contexts:

Fɔn (Kwa)

(2a) Kofi ɖɔ **émí** gba xwe **émí-tõ** ɖayi
Kofi say:that LOG build house LOG:POSS T/A
'Kofi$_i$ said that he$_i$ had built his$_i$ house'

(2b) **à** ɖɔ **émí** gba xwe
2S say:that LOG build house
émí-tõ ɖayi
LOG:POSS T/A
'You said that you had built your house'

It is worth noting that in FOn, as in other languages with this sort of syncretism, second and third person marking are distinct outside of logophoric contexts (for discussion see Roncador, 1992). Concerning plurals, it is often not the identity of plural referents which is at issue, but a relation of inclusion in that a singular S_1 may trigger a plural LOG (see Clements, 1975 for examples in Ewe). The reverse does not seem to exist.

The Status of Logophoric Constructions within Reported Discourse

By the choice of the logophoric form as such, a logophoric construction will be distinct from direct discourse. On the other hand, as Hagège (1974) and Clements (1975) noted, logophoric constructions in many languages permit elements otherwise reserved to direct discourse, such as exclamatives, vocatives, and second and even first person elements with direct discourse orientation. It has been proposed (Roncador, 1988) to treat logophors as devices to introduce a secondary subject of consciousness as in free indirect discourse (*discours indirect libre*), also called 'represented speech and thought,' the difference being that the subject of consciousness in logophoric constructions is not just reflecting but also communicating, as shown by the occurrence of vocatives or second persons:

Mundang (Adamawa) (Hagége, 1974)

(3) à fá mò ʔī̱ ʒì nē
3S say 2S see LOG PART
'He asked (him): "Did you see me?"'

The Origin of Logophors

In cases where the logophoric device also appears in other contexts, such functions are usually more marked than the 'normal' elements expressing disjoint reference in logophoric contexts. Emphatics, nonsubject pronouns, possessive reflexives, etc., may be used as logophoric devices in appropriate contexts (for discussion, including counterexamples, see Roncador, 1992). The examples in (4) illustrate the possessive reflexive (4a) contrasting with the regular 3rd person possessive (4b). In (4c), the possessive form may be interpreted as coreferring to the reported speaker (as a logophor) or to the subject of the clause (as reflexive possessive).

Bwamu (Central Gur):

(4a) à wɛ̄ mí múú
3Sg:Sbj like Poss-Refl field
'He likes his (own) field'

(4b) à wɛ̄ pɛ̄è múú
3Sg:Sbj like 3Sg:Poss field
'He$_i$ likes his$_j$ field'

(4c) yàn̄-zɔ̀n̄ nɛ̄ mí h̰í̱ń tɔ̄n
Yanzon say LOG TAM build
mí zū̱nù
LOG/Poss-Refl house
'Yanzon$_i$ said that he$_i$ had built his$_i$ house.'

Several authors have equated logophors with long-distance reflexives (Sells, 1987; Koster and Reuland, 1991; Stirling, 1993; Huang, 2002). Although there is

some functional overlap (see Suzuki, 2002 for the Japanese reflexive *zibun*, which may be used in modern literature to represent the subject of consciousness in free indirect discourse), the main difference is that long-distance reflexives may also occur bound within a clause while logophors may not. In many cases (e.g., in Latin), long-distance reflexives have a wider function than rendering speech or thought. As Comrie (2004) noted, the property that the marked value indicates coreference finds its parallels in other reference-tracking devices such as 'prodrop,' long-distance reflexives, etc. He acknowledged nevertheless that logophoricity (proper) is a unique areal characteristic of African languages not found elsewhere. Its distribution in an area north of the rain forest from the Gulf of Guinea to the Nile valley has been discussed by, amongst others, Roncador (1992), Dimmendaal (2001), and Güldemann (2003); the latter proposed the name 'Macro-Sudan' for this language area. While Roncador suggested different origins of logophoric devices through function borrowing, Dimmendaal took the occurrence of similar forms in Niger-Congo and Nilo-Saharan (see Boyeldieu, 2004 for details in a Nilo-Saharan subgroup) as proof for the Congo-Saharan hypothesis that the two stocks had a common origin. Güldemann examined three possibilities for the development of logophors: internal development, genealogical inheritance, and language contact. He suggests a connection between logophoricity and the frequency of nondirect speech in a given language. Ameka (2004) has recently argued for a connection between logophoricity and evidential marking on the one hand and the practice of triadic communication in African societies. In the communication of a chief via a spokesperson to his audience, the intermediary will usually not use direct speech to render the words of the chief; it may be felt as presumptuous to assume the same orientation. On the other hand, the use of the 'regular' third person pronoun would put the chief on the same 'level' as other third persons. This scenario might find some corroboration in the fact that in some languages, such as Bijogo (Bidyogo) (G. Segerer, personal communication), the logophoric form might be traced to a noun denoting 'owner, master'.

Lomonosov, Mikhail Vasilyevich (1711–1765)

S Archaimbault, Université Paris, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Mixail Vasilievich (Mikhail Vasilyevich) Lomonosov was born in 1711 in a small village of northern Russia (Kurostrov, Arkhangel'sk government). He was first educated by a local deacon and then, in 1730, joined the Slav-Greco-Latin Academy of Moscow, where he devoted himself to the comparative study of Slavonic and the Russian dialect. He turned out to be an outstanding student, and in 1735 he was accepted to the newly founded University of the Academy of Sciences and then sent to Marburg in 1736 to improve his knowledge of exact sciences. There, he was taught by Christian Wolff, whose *Principles of physics* he translated later on. He stands in good place in the pantheon of Russian scientists, even during the Soviet period, when his modest origins helped build the myth of the self-made scientist. His complete works were edited in the 1950s, including his comments and drafts, which are of invaluable help to researchers. He was interested in every field of knowledge and worked successively as Physics Assistant and Chemistry Professor before starting an outstanding academic career, thanks to the solicitude of Ivan Shulavov, the protégé of Empress Elisabeth Petrovna. He also wrote several books on physics, crystallography, and history and important works devoted to the study of language.

His Russian grammar (*Rossijskaja grammatika,* 1755), which was reedited several times, elaborates on the Slavonic grammar sketched in Zizanius or Smotrickij, but also describes new language facts. As the drafts show, he gathered a huge corpus, mainly lexical, and was influenced by the observation method of the natural sciences. Lomonosov's ultimate aim was to fight the Slavonic/Russian diglossia by providing the Russian language – which he considered as the first European language – with a grammar of usage, but he also wanted to describe a correct language that all social classes could share. Consequently, he adapted the 'three styles' theory (high, low, medium), using a fair proportion of slavonicisms and elements of the spoken or popular language. He linked syntax and rhetoric, relating clause to period, the period being for him the syntactic unit. Therefore, his grammar and his rhetoric should be read as complementary: They serve the same purpose, namely, that the literary language be not different from the spoken language.

Moreover, he developed his thought within the framework of General Grammar, shared by the European scientists of the time, which was a general philosophical conception of human language. He completed the grammatical terminology, integrating new terms; and in an important part devoted to phonetics, he strictly delimited grapheme and sound and finely described the point of articulation.

He also wrote a great number of odes and tragedies, and an epistle on the usefulness of glass (*Pis'mo o pol'ze stekla,* 1752), where he used the 'medium style' to pay homage to his protector I. I. Shuvalov, who was at the time setting up a glass factory near Saint Petersburg. Even though he will not be remembered as a prominent prose writer or poet, he will remain an encyclopedic mind who devoted his life to the Promethean task of constituting a Russian science capable of rivaling European science. His name is attached to the founding of the University of Moscow (1755), where all subject matters and disciplines had to be taught in Russian.

He died in 1765 in Saint Petersburg.

Long-Distance Dependencies

Y N Falk, The Hebrew University of Jerusalem, Jerusalem, Israel

© 2006 Elsevier Ltd. All rights reserved.

Basic Properties

The family of long-distance dependency constructions has been given various names in the literature. In addition to 'long-distance dependencies,' these constructions have also been called 'extraction,' 'unbounded dependencies,' '*wh* dependencies' (or '*wh* movement'), 'Ā dependencies' (or 'Ā movement'), 'syntactic binding,' 'operator movement,' and 'constituent control.' Long-distance dependency (LDD) constructions can be split into two subgroups; the constructions in Subgroup (1) are sometimes called 'strong' LDD constructions, and those in Subgroup (2) are sometimes called 'weak' constructions. Subgroup (1) (strong) constructions are exemplified by the following:

1a. *Wh* questions: Which book does the student think the teacher said the librarian put ___on the shelf?
1b. Exclamatives: What a book the student thinks the teacher said the librarian put ___ on the shelf!
1c. *Wh* relative clauses: The book [which the student thinks the teacher said the librarian put ___ on the shelf].
1d. Pseudoclefts: [What the student thinks the teacher said the librarian put ___ on the shelf] is the book.
1e. Topicalization: This book, the student thinks the teacher said the librarian put ___ on the shelf.

Subgroup (2) (weak) constructions are exemplified by the following:

2a. Non-*wh* relative clauses: The book [(that) the student thinks the teacher said the librarian put ___ on the shelf].
2b. Cleft: It is the book [that the student thinks the teacher said the librarian put ___ on the shelf].
2c. 'Tough movement': This book is easy [to think that the teacher said the librarian put ___ on the shelf].
2d. Purpose infinitive: I bought the book [for the librarian to put ___ on the shelf].

Examining an example of a strong LDD construction, such as the main clause interrogative (Subgroup (1a)), reveals the basic anatomy of these constructions. The crucial element is the underlined phrase *which book*. This phrase fulfills two distinct functions: it is both the focus of the main clause question and the object of the verb *put*. It occupies a special structural position associated with topical and focal elements (specifier of the complement phrase). The structural position normally held by the object of *put* appears to be missing. This missing position is often referred to as the 'gap,' and the fronted position is often referred to as the 'filler.' The element that appears in filler position and bears the functions associated with both filler and gap positions will be called the 'extractee' in this article.

LDD constructions, then, are filler–gap constructions. They are called long-distance (or unbounded) dependencies because there is no limit on the distance between the filler and the gap. This long-distance quality is one of the unusual features of this class of constructions; most syntactic constructions are bounded. The long-distance nature of these constructions has also led to the need to refer to parts of the constructions: the constituent containing the filler can be referred to as the 'top' of the construction, and the constituent containing the gap is the 'bottom.' The constituents in between are called the 'middle' (or 'body') of the construction. The top, middle, and bottom taken together constitute the 'path.' The extractee is said to be extracted along the path from the gap position to the filler position.

LDD constructions involve a close relation between the filler and the gap. This can be seen from the property of 'strong connectivity': syntactic requirements of the gap position (such as case marking) hold of the filler. This is hard to see in a language such as English, which has very little overt case marking, but can be clearly seen in the following example from Hebrew, wherein the topicalized noun phrase is marked with accusative case (in Hebrew, the prenominal particle *et*) because it corresponds to an object gap:

1a. *Wh* questions: Which book does the student think the teacher said the librarian put ___on the shelf?
1b. Exclamatives: What a book the student thinks the teacher said the librarian put ___ on the shelf!
1c. *Wh* relative clauses: The book [which the student thinks the teacher said the librarian put ___ on the shelf].
1d. Pseudoclefts: [What the student thinks the teacher said the librarian put ___ on the shelf] is the book.
1e. Topicalization: This book, the student thinks the teacher said the librarian put ___ on the shelf.

Subgroup (2) (weak) constructions are exemplified by the following:

2a. Non-*wh* relative clauses: The book [(that) the student thinks the teacher said the librarian put ___ on the shelf].
2b. Cleft: It is the book [that the student thinks the teacher said the librarian put ___ on the shelf].
2c. 'Tough movement': This book is easy [to think that the teacher said the librarian put ___ on the shelf].
2d. Purpose infinitive: I bought the book [for the librarian to put ___ on the shelf].

Examining an example of a strong LDD construction, such as the main clause interrogative (Subgroup (1a)), reveals the basic anatomy of these constructions. The crucial element is the underlined phrase *which book*. This phrase fulfills two distinct functions: it is both the focus of the main clause question and the object of the verb *put*. It occupies a special structural position associated with topical and focal elements (specifier of the complement phrase). The structural position normally held by the object of *put* appears to be missing. This missing position is often referred to as the 'gap,' and the fronted position is often referred to as the 'filler.' The element that appears in filler position and bears the functions associated with both filler and gap positions will be called the 'extractee' in this article.

LDD constructions, then, are filler–gap constructions. They are called long-distance (or unbounded) dependencies because there is no limit on the distance between the filler and the gap. This long-distance quality is one of the unusual features of this class of constructions; most syntactic constructions are bounded. The long-distance nature of these constructions has also led to the need to refer to parts of the constructions: the constituent containing the filler can be referred to as the 'top' of the construction, and the constituent containing the gap is the 'bottom.' The constituents in between are called the 'middle' (or 'body') of the construction. The top, middle, and bottom taken together constitute the 'path.' The extractee is said to be extracted along the path from the gap position to the filler position.

LDD constructions involve a close relation between the filler and the gap. This can be seen from the property of 'strong connectivity': syntactic requirements of the gap position (such as case marking) hold of the filler. This is hard to see in a language such as English, which has very little overt case marking, but can be clearly seen in the following example from Hebrew, wherein the topicalized noun phrase is marked with accusative case (in Hebrew, the prenominal particle *et*) because it corresponds to an object gap:

(1) Et hasefer haze, hasafranit
ACC the.book the.this the.librarian
lo tasim ___ al hamadaf.
not will.put on the.shelf
'This book, the librarian won't put on the shelf.'

Weak LDD constructions have essentially the same structure as strong ones have. The difference, as can be seen in the Subgroup (2) examples, is that they appear to lack a filler. Nevertheless, they display all the LDD phenomena discussed in the following section.

Long-Distance Dependency Phenomena

Islands

The most discussed phenomenon in LDD is 'islands,' which are structures that an LDD path cannot cross. Many of the island constraints were originally stated and named by Ross (1967). One island constraint, the coordinate structure constraint, prohibits extraction from one conjunct of a coordinate structure:

(2a) The librarian [[put these books on the shelf] and [then took a break].
(2b) *Which books did the librarian [[put ___ on the shelf] and [then take a break]]?

(3a) The librarian put [[books] and [magazines]] on the shelf.
(3b) *What did the librarian put [___ and magazines] on the shelf?

On the other hand, 'across-the-board' (or ATB) extraction from both conjuncts is grammatical:

(4a) The librarian [[recorded these books in the catalog] and [put these books on the shelf].
(4b) Which books did the librarian [[record ___ in the catalog] and [put ___ on the shelf]]?

Another island constraint is the left branch condition, which prohibits the extraction of prehead (left) dependents in noun phrases and adjective phrases:

(5a) The librarian put [my book] on the shelf.
(5b) *Whose did the librarian put [___ book] on the shelf?

(6a) That book is [extremely interesting].
(6b) *How is that book [___ interesting]?

Elements bearing certain grammatical functions constitute islands. For example, extraction is forbidden from subjects:

(7a) [Books about wayward librarians] shocked me.
(7b) *Who did [books about ___] shock you?

Adjuncts are also islands:

(8a) I screamed [after the librarian put that book on the shelf].
(8b) *Which book did you scream [after the librarian put ___ on the shelf]?

However, some speakers find the adjunct condition to be weaker than the subject condition.

Some island constraints produce violations that can either be relatively acceptable or totally unacceptable, depending on the circumstances. One such constraint is the complex noun phrase (NP) constraint, which prohibits extraction from a clause within a noun phrase. Extraction from a complement clause (Examples (9a) and (9b)) is not as bad as extraction from a relative clause (Examples (10a) and (10b)), because the latter combines the complex NP constraint with the adjunct constraint:

(9a) I heard [a rumor [that the librarian put that book on the shelf]].
(9b) ?*Which book did you hear [a rumor [that the librarian put ___ on the shelf]]?

(10a) I saw [the librarian [who put that book on the shelf]].
(10b) *Which book did you see [the librarian [who put ___ on the shelf]]?

Another such island constraint is the *wh* island constraint, which rules out extractions from *wh* clauses (clauses introduced by *wh* elements). Extraction from nonfinite *wh* clauses (as in Examples (11a) and (11b)) is not totally unacceptable, but extraction from finite *wh* clauses (as in Examples (12a) and (12b)) is much worse:

(11a) The librarian wondered [whether to put that book on the shelf].
(11b) ?Which book did the librarian wonder [whether to put ___ on the shelf]?

(12a) I wondered [whether the librarian put that book on the shelf].
(12b) *Which book did you wonder [whether the librarian put ___ on the shelf]?

Another ungrammatical LDD involves the extraction of a subject following a complementizer; this is known as the *that*-trace effect. Extraction of a subject is grammatical in the absence of the complementizer, and extraction of nonsubjects is not sensitive to the presence of a complementizer:

(13a) I think [the librarian put the book on the shelf].
(13b) Who do you think [___ put the book on the shelf]?
(13c) What do you think [the librarian put ___ on the shelf]?

(14a) I think [that the librarian put the book on the shelf].
(14b) *Who do you think [that ___ put the book on the shelf]?

(14c) What do you think [that the librarian put ___ on the shelf]?

Pied-Piping

Sometimes the filler involves more than just the element that is being focused on or topicalized. Often this is done as a way of circumventing island constraints. So, whereas Example (15a) is ungrammatical (ruled out by the left branch condition), it is possible to front the larger NP, as in Example (15b), even though it is only the possessor of the book that is being questioned:

(15a) *Whose did the librarian put [___ book] on the shelf?
(15b) Whose book did the librarian put ___ on the shelf?

This phenomenon was dubbed 'pied-piping' by Ross (1967). Pied-piping is sometimes a stylistic option; for example, instead of extracting the object of a preposition and leaving the preposition stranded, which is grammatical but stigmatized in certain styles of English, the prepositional phrase can be pied-piped:

(16a) Which shelf did the librarian put the book [on ___]?
(16b) On [which shelf] did the librarian put the book ___ ?

Crossover

LDD constructions interact with pronominal coreference. The position (or grammatical function) of the gap influences coreferential possibilities. Roughly speaking, if the gap is structurally lower than the pronoun, coreference is impossible even though the filler position occupied by the extractee is higher:

(17a) Who$_i$ did you say ___ thinks the librarian hates him$_i$?
(17b) *Who$_i$ did you say he$_i$ thinks the librarian hates ___ ?

The ungrammaticality of Example (17b) has been named crossover because, in a transformational account, the extractee crosses over a coreferential NP. That is to say, in this example, *who* crosses over the coreferential *he*. A weaker crossover effect obtains if the pronoun is embedded:

(18a) Who$_i$ did you say ___ thinks the librarian hates [his$_i$ students]?
(18b) ?*Who$_i$ did you say [his$_i$ students] think the librarian hates ___ ?

The effect in Example (17b) is called strong crossover, and that in Example (18b) is weak crossover.

Parasitic Gaps

A phenomenon that has received much attention in the literature on LDDs since the 1980s is illustrated by the following example:

(19) Which books did the librarian put ___ on the shelf before reading ___ ?

In this sentence, there is one filler, but two gaps. The filler corresponds to both of these gaps. The existence of two gaps corresponding to a single filler is strange; more strange is that the second gap, being embedded within an adjunct, would normally be ungrammatical (because of the adjunct condition), and thus can be thought of as relying on the first gap for its existence. The second gap is said to be parasitic on the first (true) gap, and this construction is referred to as the 'parasitic gap' construction. Despite a rather large literature on parasitic gaps, many open questions remain. Even the connection with ordinary LDD constructions is called into question by the fact that parasitic gaps are possible in heavy NP shift constructions, which do not have the same properties as LDDs have:

(20) The librarian put ___ on the shelf without reading ___ first [a very expensive edition of Chomsky's classic book *Syntactic structures*].

Other non-LDD constructions in other languages, such as scrambling and object clitic constructions, have also been observed to license parasitic gaps. Culicover (2001) provided a good overview of the literature on the subject.

Path Phenomena

In some languages, clauses on the path of an LDD exhibit morphosyntactic properties that distinguish them from ordinary clauses. A survey of such cases is provided by Zaenen (1983). These include a complementizer selection in Irish, a tonal phenomenon (downstep deletion) in Kikuyu (Gikuyu), a 'stylistic' subject–verb inversion in French, and the nonuse of the pleonastic element *?það* in Icelandic. The following examples from Irish illustrate this: the normal complementizer is *goN*, but the complementizer on a path is *aL* (the capitals *N* and *L* indicate phonological nasalization or lenition of the following consonant). The complementizer *aL* is used in all and only clauses on the path.

(21) Deir siad goN síleann an t-athair
say they that thinks the father
goN bpósfaidh Síle é.
that will.marry Sheila him
'They say that the father thinks Sheila will marry him.'

(22) An fear [aL deir siad [aL shíleann
the man that say they that thinks
an t-athair [aL phósfaidh Síle ___]]].
the father that will.marry Sheila
'The man that they say the father thinks Sheila will marry.'

(23) An fear [aL shíl ___ [goN mbeadh sé ann]].
the man that said that would.be he there
'The man that said that he would be there.'

Path phenomena are important in understanding LDD constructions because they show that the middle of the construction has syntactic relevance. The relevance of the middle of the construction is not surprising. As noted earlier in this article, the long-distance nature of LDD constructions is surprising: syntax usually operates on more local domains. The necessity of a clause-by-clause (or constituent-by-constituent) theory of LDDs is therefore expected. All of the contemporary theoretical analyses discussed in the following sections have a local component to them, and are thus compatible with the existence of path phenomena.

Reconstruction Effects

Another property of LDDs is what has been referred to as reconstruction effects. Reconstruction refers to the extractee, which occupies filler position, having semantic properties that make it appear as if it is in the position of the gap. For example, note the reflexive *herself* in the following example:

(24) Which book about herself$_i$ does he think the teacher said the librarian$_i$ put ___ on the shelf?

The reflexive here is part of the filler. A reflexive (roughly) needs to have its antecedent higher in the structure and within its clause, but in this case the antecedent is lower in the structure. What makes this sentence grammatical is that the antecedent is in the correct position for the reflexive if the reflexive is seen as part of the gap. Like strong connectivity, reconstruction effects are an indication of the close relationship between the filler and gap. They suggest, as is embodied in all contemporary standard analyses of LDDs, that the extractee is associated with both filler and gap positions/functions.

Resumptive Pronouns

Many languages allow or require a pronoun in place of the gap in certain types of LDD constructions. This pronoun is called a 'resumptive pronoun.' For example, in Hebrew relative clauses, when the extractee is the object of a verb, a resumptive pronoun is optional; when the extractee is the object of a preposition, a resumptive pronoun is obligatory:

(25a) Hasefer še hasafranit sama ___
the.book that the.librarian put
al hamadaf.
on the.shelf
'The book that the librarian put on the shelf.'

(25b) Hasefer še hasafranit sama oto
the.book that the.librarian put it
al hamadaf.
on the.shelf
'The book that the librarian put (it) on the shelf.'

(26a) *Hamadaf še hasafranit sama
the.shelf that the.librarian put
al___ et hasefer.
on ACC the.book
'The shelf that the librarian put the book on.'

(26b) Hamadaf še hasafranit sama al-
the.shelf that the.librarian put on-
av et hasefer.
it ACC the.book
'The shelf that the librarian put the book on (it).'

Resumptive pronouns are usually immune from island constraints and do not normally trigger path phenomena. They may or may not display crossover effects or license parasitic gaps. Thus, although they are LDD constructions, they differ from gap-containing constructions. Often, resumptive pronouns are used as a way of circumventing island constraints. For many speakers of English, resumptive pronoun constructions, although not entirely grammatical, seem better than island violations with gaps:

(27a) *The book that I saw the librarian who put ___ on the shelf?

(27b) ??The book that I saw the librarian who put it on the shelf?

(28a) *Who did you ask whether ___ put the book on the shelf?

(28b) ??Who did you ask whether she put the book on the shelf?

The analysis of LDD constructions with resumptive pronouns is more controversial than that of LDD constructions with gaps, and will not be discussed here.

Analysis

Discussions in the following sections outline the analysis of LDDs in the major current streams of syntactic theory. The important aspects of the analyses will be covered without involving theory-internal technicalities.

Transformational Grammar

The informal description of LDDs in the preceding sections, given in terms of extraction of the extractee

from the gap position to the filler position, corresponds to the transformational analysis of these constructions. In the underlying (deep) structure, the extractee occupies the gap position, whereas in surface structure, it occupies filler position. In the earliest work in transformational grammar (such as that of Chomsky (1957)), it was taken for granted that LDD constructions were derived by transformation:

(29) Deep structure: the librarian PAST put [which book] on the shelf.
Surface structure: [which book] did the librarian put on the shelf.

The deep structure location of the extractee in the position of the gap is natural, given the fact that the extractee fulfills selectional properties of the verb and is interpreted as an argument. Subsequent development of the theory has refined this view somewhat. For example, since the introduction by Chomsky (1973) of the idea that movement leaves a trace, it has been standard to hypothesize a surface trace (*t*) in the underlying position of the extractee:

(30) [which book] did the librarian put *t* on the shelf

In some versions of the theory, this trace is co-indexed with the filler, and/or forms a syntactic object called a chain with it (see, for example, Chomsky (1981)). Since a chain is a single syntactic object, with a single set of syntactic properties, strong connectivity follows naturally in such a system. It has also been proposed (Chomsky, 1995, 2000) that movement is a copying operation, and the trace is therefore a copy of the filler: this accounts naturally for reconstruction effects, since the extractee occupies both structural positions. The trace has also been endowed with the semantic status of a variable at the level of logical form, bound by the quantifier-like *wh* operator (Chomsky, 1977). This variable, because it is semantically similar to a name, is said to have the binding-theoretic status of ordinary referential NPs. This accounts for strong crossover effects, because strong crossover involves the forbidden anaphoric binding of the variable by a pronoun (Chomsky, 1981). The filler position, being a nonargument (Ā) position, does not anaphorically bind the variable.

In the earliest transformational analyses, the extractee moved in strong constructions and deleted in weak constructions. Unlike clause-bounded rules, like passive, LDD rules were stated with a variable intended to cover an arbitrary string of constituents, thus capturing their long-distance nature. Islands were taken to be the result of constraints on the interpretation of these variables (Ross, 1967). A more uniform approach to (most) islands was developed in the form of the subjacency condition (Chomsky, 1973), which limited the distance of movement. Much subsequent work has focused on determining the exact nature of this limitation, but (roughly) the bounding nodes are a clausal node and NP. Apparently long-distance movement is taken to be derived by successive movements from specifier of complement phrase (CP) to specifier of CP:

(31) Which book$_i$ does the student think [t_i the teacher said [t_i that the librarian put t_i on the shelf]]?

Under this view, most islands follow from the lack of an appropriate intermediate landing site. (Certain other islands are the result of the empty category principle, a locality condition on the trace (Chomsky, 1981).)

The subjacency-based approach to islands made the deletion analysis of weak LDD constructions untenable. Chomsky (1977) proposed that there is a single transformational rule 'move *wh*' that is responsible for all LDDs; in weak LDD constructions, the *wh* subsequently deletes (Chomsky, 1977) or is a phonologically empty null operator (*Op*) (Chomsky, 1981):

(32) the book [*Op* (that) the student thinks [*t* the teacher said [*t* the librarian put *t* on the shelf]]]

Transformational theory has also been concerned with the motivation of *wh* movement. For example, Chomsky (1986) suggested that *wh* movement is necessary for the *wh* operator to assume the correct scope at logical form. Chomsky (1995) also attributed *wh* movement to the need to have features checked: the interrogative complementizer carries a *wh* feature that needs to be checked. Moving a *wh* element to its specifier allows the checking.

Phrase Structure Grammar

Since the class of LDD constructions is one of the types of constructions that has been generally accepted as showing that natural-language syntax cannot be described by phrase structure grammar, one of the earliest efforts in contemporary phrase structure grammar has been to show that this assumption is false. Thus the earliest work in generalized phrase structure grammar (GPSG) by Gazdar *et al.* (1984) dealt with these constructions, and the basic ideas developed in that work have been carried over into head-driven phrase structure grammar (HPSG) (Pollard and Sag, 1994).

The basic idea in the GPSG/HPSG analysis is that the constituent containing the gap has a special 'missing element' feature. Informally, this is written

using a slash: for example, a verb phrase (VP) with a missing NP belongs to the category VP/NP. As a result of this notation, the feature has come to be named SLASH. In the following sentence (Example (33)), the constituent headed by *put* is a VP/NP. The clausal constituent containing this VP/NP is S/NP, since it is missing the same NP as the VP it dominates:

(33) [$_{S}$ Which book [$_{S/NP}$ does the student [$_{VP/NP}$ think [$_{S/NP}$ the teacher [$_{VP/NP}$ said [$_{S/NP}$ the librarian [$_{VP/NP}$ put [$_{NP/NP}$ *e*] on the shelf]]]]]]]?

A category such as S/NP is S with the additional feature [SLASH ⟨NP⟩]. More precisely, the elements of the value of SLASH are not category labels, but (part of) the feature structure of the filler. As a result of this feature sharing, the same element occupies the filler and gap positions simultaneously, without movement. This accounts for strong connectivity and reconstruction effects. The SLASH feature is said to be introduced at the bottom of the construction and discharged (or bound off) at the top.

The passing of the SLASH feature up the tree has an unusual quality to it, as it appears not to based on the concept of head. In much of the GPSG/HPSG literature, SLASH is said to belong to a special class of features, called nonlocal (or foot) features, which are not constrained to percolate between heads and phrases. A different account (Bouma *et al.*, 2001; Ginzburg and Sag, 2000) proposed that the head amalgamates all the SLASH values of its dependents, so the SLASH feature on a phrase in the path is inherited from the head. This obviates the need for a special kind of feature.

In early GPSG/HPSG literature, the gap was viewed (in most cases) as an empty category (trace), as in transformational theory. However, what has become the standard view (originating in the work of Pollard and Sag (1994)) is one in which the SLASH feature originates not in a trace but rather as one of the features of the selecting head. Even in early work, traces did not appear in all LDDs: a distinction was drawn between subject extraction (which did not involve a trace) and nonsubject extraction (which did). In the work of Bouma *et al.* (2001), Sag (2001), and Ginzburg and Sag (2000), subject and nonsubject extraction (and adjunct extraction) have been unified. The issues involved here have been primarily theory-internal issues of the nature of the features involved. However, questions of similarities and differences between subject and nonsubject extraction have also been raised: proponents of the earlier view have cited differences between subject and nonsubject extraction, whereas proponents of the more recent view have cited similarities. As is generally the case in HPSG, the properties of LDD constructions are a consequence of the properties of feature structures. Island constraints are due to constraints on feature combinations. The discharge of the SLASH feature is due to the properties of feature-based constructions. The lack of a filler in weak constructions is not a problem, as the construction can bind off the SLASH feature, even without a filler.

Lexical-Functional Grammar

Lexical-functional grammar (LFG) (Kaplan and Bresnan, 1982; Bresnan, 2001) models syntax as involving parallel representations of structure (known as constituent structure, or c-structure) and function (functional structure, or f-structure). At f-structure, the multifunctionality of elements in LDD constructions is represented directly. For example, as was shown in Example (33), the functional element corresponding to the determiner phrase *which book* fills both the function of FOCUS of the main clause (the clause headed by *think*) and OBJECT of the clause headed by *put*. Such a representation differs from other theories, particularly transformational theory, in not conceptualizing LDD constructions as involving the displacement of an element from its natural position. Instead, the element has two functions, and the c-structural position that it occupies is the canonical position of one of those two functions. Strong connectivity and reconstruction effects follow, since the phenomena in question are f-structure phenomena, and the extractee has both the filler function and the gap function simultaneously. Since LDD constructions are an f-structure phenomenon, the lack of an overt c-structure filler in weak LDD constructions is not a problem.

The currently accepted view (Kaplan and Zaenen, 1989) is that the licensing of LDD constructions is purely a functional structure matter, and is not based on constituent structure properties. The licensing takes the form of a constraint schema identifying the values of two grammatical functions. The constraint schema, which represents an infinite number of specific constraints, has come to be referred to as 'functional uncertainty.' There are several reasons given for treating LDD constructions as being licensed at f-structure; for example, these constructions exhibit category mismatches:

(34a) That he might be wrong, he didn't think of.
(34b) *That he might be wrong, he didn't think.
(34c) *He didn't think of that he might be wrong.
(34d) He didn't think that he might be wrong.

Another argument is that islands are based on grammatical functions such as subject and adjunct, not on structural position. Kaplan and Zaenen (1989) gave

arguments that, in general, islands are due to functional constraints on the middle of the construction. Although Kaplan and Bresnan's (1982) original formulation hypothesized a trace in the position of the gap, this is not necessary under Kaplan and Zaenen's functional uncertainty approach: a constraint associated with the position of the filler specifies the gap function. However, an alternative to the traceless c-structure proposed by Kaplan and Zaenen has been proposed by Bresnan (1995). Bresnan licensed the multifunctionality of the extractee through bottom-up ('inside-out' in the terminology used in LFG) functional uncertainty: the licensing constraint is associated with the empty element and expresses identity with a grammaticized discourse function higher in the structure. Falk (2001) proposed that subject extraction be distinguished from nonsubject extraction: he analyzed subject extraction the way Kaplan and Zaenen did, using top-down (outside-in) licensing without trace, and nonsubject extraction using Bresnan's empty category with bottom-up (inside-out) licensing. He suggested that certain differences between subjects and nonsubjects can be accounted for in this fashion. Falk's analysis bears some resemblance to the early distinction in GPSG/HPSG between subject and nonsubject extraction.

Traces

As the descriptions of the analyses of LDD constructions in various theories demonstrate, one of the major areas of disagreement is the structural status of the gap position. Some researchers analyze all gap positions as containing an empty category (or trace), some analyze some gap positions (nonsubjects) as containing traces and other gap positions (subjects) as not containing them, and some hold that there is never an empty element in the position of the gap. To a degree, the question of the presence of traces is a theory-internal matter. In transformational theory, for example, traces are part of the general theory of movement. Conversely, for proponents of traceless accounts, the fact that traces are not overt elements makes them suspect as elements of constituent structure. Nevertheless, there have been attempts in the literature to find overt evidence for traces in LDD constructions. This suggests that at least some researchers consider the question of the existence of traces to be an empirical question. The following discussions review some of the more well-known arguments that have appeared in the literature. Ironically, although nonderivational theories tend to be more skeptical about traces than derivational theories do, it was the original proposal that movement leaves a trace that provided the initial impetus for nontransformational theories of LDD constructions. Once traces were proposed, the original argument for deep structure and movement carried less weight: as long as there was a mechanism for associating the trace with the extractee, there was no need to posit an abstract structure in which the extractee occupies the position of the gap. The trace was there to serve whatever functions the deep structure position of the extractee was intended to serve, such as fulfilling selectional properties and having the clause-internal grammatical function.

The best known argument for traces is the phenomena of *wanna* contraction. In natural speech, the sequence *want to* is normally pronounced *wanna*:

(35) I want to put the book on the shelf → I wanna put the book on the shelf.

But if there is an LDD gap between *want* and *to*, this is impossible for most speakers of English:

(36) Who do you want ___ to put the book on the shelf? ↛
*Who do you wanna put the book on the shelf?

This argument for traces was summarized by Jacobson (1982). However, other analyses of *wanna* contraction have been proposed. For example, the ability to contract can be defined in terms of subject sharing: it is possible when the subject of *want* is the same as the subject of *to*'s clause (Postal and Pullum, 1978). Alternatively, *wanna* may be a lexical item, with no contraction involved at the syntactic level (Pullum, 1997). The argument from *wanna* contraction is thus at best inconclusive.

Jacobson (1982) cited several additional arguments for traces. One of them is based on the fact that the VP following *to* can normally be ellipted, but not immediately following a gap:

(37a) The students hope to ~~put the books on the shelf~~.
(37b) *Who did you ask ___ to ~~put the books on the shelf?~~.
(37c) Who did you ask ___ not to ~~put the books on the shelf?~~.

Jacobson hypothesized that the constituent before *to* in a VP ellipsis construction must be stressed. Since trace cannot be stressed, the ellipsis is ungrammatical.

Another argument for traces has been advanced by Bresnan (1995). She argued that weak crossover effects are due to syntactic rank (defined in terms of a hierarchy of grammatical functions) and linear order. She noted that, in the following examples, syntactic rank cannot be the cause, since obliques outrank predicative (Example (38a)) and clausal (Example (38b)) complements, and different obliques have the same rank (Example (38c)):

(38a) ?*To whom$_i$ did Mary seem proud of him$_i$ ___ ?
(38b) ??Who(m)$_i$ did they explain how he$_i$ should dress to ___ ?
(38c) ?*Everyone$_i$ in the room, I talked about his$_i$ coursework with ___.

The weak crossover effects in these sentences must be due to the pronoun preceding its intended antecedent, which is possible only if there is a trace in the gap position.

Pollard and Sag (1994) cited psycholinguistic evidence against the idea that traces can be shown to be in the position where the filler is reactivated. The evidence instead seems to indicate that reactivation occurs at the position of the selecting head rather than at the position of the gap. They noted that the sentence in Example (39a), in which the selecting head (*in*) follows the heavy NP object, is difficult to process, but the sentence in Example (40b), in which the selecting head (*put*) precedes the heavy NP, is not difficult to process, despite the fact that the putative trace would follow the NP:

(39a) Which box did you put the very large and beautifully decorated wedding cake bought from the expensive bakery in ___ ?
(39b) In which box did you put the very large and beautifully decorated wedding cake bought from the expensive bakery ___ ?

The evidence for the existence of traces in LDD constructions is inconclusive at this stage. More research is needed to determine whether there is empirical evidence for them. For now, it remains a theory-internal question.

Long-Range Comparison: Methodological Disputes

L Campbell, University of Utah, Salt Lake City, UT, USA

Introduction

How are languages shown to be related to one another? Proposals of distant linguistic kinship such as Amerind, Nostratic, Eurasiatic, and Proto-World have received much attention in recent years, although these same proposals are rejected by a majority of practicing historical linguists. This has resulted in vigorous disputes about the methods for investigating remote relationships among languages as yet not known to be related. Some enthusiasts of long-range relationships, disappointed that proposed language connections they favor have not been accepted, have at times responded bitterly, for example charging that these rejections are just "clumsy and dishonest attempts to discredit deep reconstructions" (Shevoroshkin, 1989: 7), and that "very few [critics of long-range proposals] have ever bothered to examine the evidence first-hand... To really screw up classification you almost have to have a Ph.D. in historical linguistics" (Ruhlen, 1994: viii). The strong rhetoric is not all one-sided:

> At a different level – which transcends scientific worth to such an extent that it is at the fringe of idiocy – there have in recent years been promulgated a number of far-fetched ideas concerning 'long-distance relationships', such as 'Nostratic', 'Sino-Caucasian', and 'Amerind'. (Dixon, 2002: 23)

This article explains these disputes.

Hypothesized Long-Range Relationships

The list in Table 1 of the better-known hypotheses that would group together languages that are not yet known to be related gives an idea of what is at issue. (None of the proposed genetic relationships in this list has been demonstrated yet, even though some are repeated frequently.)

Methods

Scholars agree that a successful demonstration of linguistic kinship depends on adequate methods, but disagree about what these methods are. Hence discussions of methodology assume a central role in considerations of long-range comparisons. Therefore, the methodological principles and criteria considered important for investigating proposals of distant genetic relationship are surveyed here.

In practice, the successful methods for establishing distant linguistic affinity have not been different from those used to establish any family relationship, close or distant. The comparative method has always been the primary tool. Because the methods for distant relationships are not different from those for more closely related languages, we encounter a continuum from established families (e.g., Indo-European, Finno-Ugric, Mayan, Bantu), to more distant but solidly demonstrated relationships (e.g., Uralic, Siouan-Catawban, Benue-Congo), to plausible but inconclusive hypotheses (e.g., Indo-Uralic, Proto-Australian, Macro-Mayan, Niger-Congo), to doubtful but not implausible ones (e.g., Altaic, Austro-Tai, Eskimo-Uralic, Nilo-Saharan), and on to virtually impossible proposals (e.g., Basque-SinoTibetan-NaDene, Indo-Pacific Mayan-Turkic, Miwok-Uralic, Niger-Saharan). It is difficult on the basis of standard methods to segment this continuum so that plausible proposals based on legitimate procedures fall sharply on one side, distinguished from obviously unlikely hypotheses on the other side. This leads to disagreements, even by those who profess allegiance to the same methods.

A firm understanding of methodology becomes crucial if supporters of fringe proposals can pretend to apply the same methods as those employed for more plausible ones. For this reason, careful evaluation of the evidence presented on behalf of any proposed distant linguistic relationship and of the methods employed is called for.

Throughout history, the criteria employed in both pronouncements about method and in actual practice for establishing language families consistently included evidence from three sources: basic vocabulary, grammatical evidence (especially morphological), and sound correspondences. Hoenigswald (1990: 119–120) summarized the points upon which 17th- and 18th-century linguistic scholars agreed:

> There was ... "a concept of the development of languages into dialects and of dialects into new independent languages" ... and ... "an insistence that not a few random items, but a large number of words from the **basic vocabulary** should form the basis of comparison" ... the doctrine that '**grammar**' is even more important than words; ... the idea that for an etymology to be valid the **differences in sound** – or in 'letters' – **must recur** [emphasis added, LC].
>
> These criteria figured prominently in nearly all demonstrations of language families in the past, making them important also to today's practice. The methods and criteria generally thought necessary for reliable long-range comparison are surveyed in what follows. (See Campbell, 2003; Campbell, 1997a: 206–259 for details.)

Table 1 Proposals of distant genetic relationships among languages

Altaic (Turkic, Tungusic, Mongolian, sometimes Japanese, Korean)
Amerind (uniting all Native American language families, except Eskimo-Aleut and Na-Dene)
Dene-Sino Tibetan (Athabaskan [or Na-Dene] and Sino-Tibetan)
Austric (Austro-Asiatic with Austronesian)
Austro-Tai (Japanese-Austro-Thai)
Basque-Caucasian, Basque-Sino Tibetan-NaDene
Dravidian-Uralic
Eskimo and Indo-European
Eskimo-Uralic
Eurasiatic (Indo-European, Uralic, Eskimo-Aleut, Ainu, several others)
Hokan (grouping numerous American Indian families and isolates)
Indo-European and Afroasiatic, Indo-European and Semitic
Indo-Pacific (grouping the non-Austronesian languages of the Pacific: all Papuan families, Tasmanian, languages of the Andaman Islands)
Japanese-Austronesian
Khoisan (grouping most non-Bantu African click languages, an areal grouping, not a genetic one)
Macro-Siouan (Siouan, Iroquoian, Caddoan, sometimes Yuchi)
Maya-Chipayan (Mayan, Uru-Chipayan of Bolivia)
Na-Dene (Eyak-Athabaskan, Tlinglit, Haida; Haida is highly disputed)
Niger-Kordofanian (Niger-Congo) (grouping Mande, Kru, Kwa, Benue-Congo [of which Bantu is a branch], Gur, Adamawa-Ubangi, Kordofanian, etc.)
Nilo-Saharan (most of the African languages not otherwise classified with one of Greenberg's other three African macrofamilies)
Nostratic (Indo-European, Uralic, Altaic, Kartvelian, Dravidian, Afroasiatic; some add others)
Penutian (grouping numerous American Indian families and isolates)
Proto-Australian (all Australian families)
Proto-World (uniting all the world's languages)
Ural-Altaic (Uralic and Altaic)

Lexical Comparison

Throughout history, word comparisons have been employed as evidence of language family relationship, but, given a small collection of likely-looking words, how can we determine whether they are really the residue of common origin and not due to chance or some other factor? Lexical comparisons by themselves are seldom convincing without additional support from other criteria.

Basic Vocabulary Most scholars require that basic vocabulary be part of the supporting evidence for any distant genetic relationship. Basic vocabulary is generally understood to include terms for body parts, close kinship, frequently encountered aspects of the natural world (mountain, river, cloud), and low numbers. Basic vocabulary is generally resistant to borrowing, so comparisons involving basic vocabulary items are less likely to be due to diffusion and stand a better chance of being inherited from a common ancestor than other kinds of vocabulary. Still, basic vocabulary can also be borrowed – though infrequently – so that its role as a safeguard against borrowing is not foolproof.

Glottochronology Glottochronology, now mostly abandoned, aimed at assigning dates to the split up of related languages; it has been employed in long-range comparisons. It depends on basic, relatively culture-free vocabulary, but all its basic assumptions have been challenged (including the existence of culture-free vocabulary). Most tellingly, it does not find or test distant genetic relationships, but rather it **assumes** that the languages compared are related and proceeds to attach a date based on the number of core-vocabulary words that are considered similar among the languages compared. This, then, is no method for determining whether languages are related.

Multilateral Comparison The best-known approach that relies on inspectional resemblances among words is Joseph Greenberg's 'multilateral (or mass) comparison.' It is based on "looking at … many languages across a few words" rather than "at a few languages across many words" (Greenberg, 1987: 23). The lexical similarities determined by superficial visual inspection that are shared 'across many languages' alone are taken as sufficient evidence for genetic relationship. This approach stops where others begin, at assembling lexical similarities. These inspectional resemblances must be investigated to determine why they are similar, whether the similarity is due to inheritance from a common ancestor (genetic relationship), or to borrowing, accident, onomatopoeia, sound symbolism, or nursery formations – nongenetic factors. Since multilateral comparison does not do this, its results are controversial and rejected by most mainstream historical linguists.

No technique that relies on inspectional similarities in vocabulary alone has proven adequate for establishing family relationships.

Sound Correspondences

Nearly all scholars consider regular sound correspondences strong evidence of genetic affinity. Correspondences do not necessarily involve similar sounds. The sounds that are equated in proposals of remote relationship are typically similar, often identical, although such identities are not so frequent among the daughter languages of well-established language families. The sound changes that lead to such

nonidentical correspondences often make cognate words not apparent. These true but nonobvious cognates are missed by methods that seek only superficial resemblance, for example: French *cinq*/Russian *pjatj*/Armenian *hing*/ English *five* (all derived by straightforward changes from original Indo-European **penkwe-* 'five'); French *boeuf*/English *cow* (both from Proto-Indo-European **gwou-* 'cow'). The words in these cognate sets are not visually similar, but they exhibit regular sound correspondences among the cognates.

Though extremely important and valuable, the criterion of sound correspondences can be misapplied. Sometimes regularly corresponding sounds are found in loans. By Grimm's law, real French-English cognates should exhibit the correspondence *p* : *f*, as in the cognates *père/father, pied/foot, pour/for.* However, French and English appear to correspondence *p* : *p* in cases where English has borrowed from French or Latin, as in *paternel/paternal, piédestal/pedestal, per/per.* Since English has many such loans, examples of the bogus *p* : *p* sound correspondence are not hard to find. In comparing languages not yet known to be related, we must be cautious of the problem of seeming correspondences in undetected loans. Sound correspondences in basic vocabulary help, since basic vocabulary is borrowed only infrequently.

Some nongenuine sound correspondences can come from accidentally similar words. Languages share some vocabulary by sheer accident, for example: Proto-Je **niw* 'new'/English *new*; Kaqchikel *mes* 'mess'/English *mess;* Maori *kuri* 'dog'/English *cur*; Lake Miwok *hóllu* 'hollow'/English *hollow*; Gbaya *be* 'to be'/English *be*. Other unreal sound correspondences can come from wide semantic latitude in proposed cognates, when phonetically similar but semantically disparate forms are equated. For example, if we compare Pipil (Uto-Aztecan) *teki* 'to cut'/ Finnish (Uralic) *teki* 'made', *tukat* 'spider'/*tukat* 'hairs', etc., we note a recurrence of a *t* : *t* and a *k : k* correspondence. However, the phonetic correspondences in these word pairs are accidental – it is always possible to find phonetically similar words among languages if their meanings are ignored. With too much semantic leeway among compared forms, spurious correspondences such as the Pipil-Finnish *t* : *t* and *k : k* turn up. Unfortunately, wide semantic latitude is very common in cases of long-range comparison. Additional noninherited phonetic similarities crop up when onomatopoetic, sound-symbolic, and nursery forms are compared. A set of proposed cognates involving a combination of loans, chance enhanced by semantic latitude, onomatopoeia, and such factors can exhibit false sound correspondences. For this reason, some proposed remote relationships that purportedly are based on regular sound correspondences nevertheless fail to be convincing.

Grammatical Evidence

Scholars throughout linguistic history have considered morphological evidence important for establishing language families. Many favor 'shared aberrancy' ('submerged features,' 'morphological peculiarities,' 'arbitrary associations'). For example, the Algonquian-Ritwan hypothesis, which groups Wiyot and Yurok (both of California) with the Algonquian family, was controversial, but morphological evidence such as the following comparison of Proto-Central-Algonquian (PCA) and Wiyot helped to confirm the relationship:

Proto-Central-Algonquian **ne* + **ehkw-*
= **netehkw-*'my louse'
Wiyot *du-* + *híkw* = *dutíkw* 'my louse' (Teeter, 1964: 1029)

Proto-Central-Algonquian inserts *-t* between a possessive pronominal prefix and a vowel-initial root, while Wiyot inserts *-t-* between possessive prefixes and a root beginning in *hV* (with the loss of the *h* in this process). There is no phonetic reason why *t* should be added in this environment; this is so unusual it is not likely to be shared by borrowing or accident. Inheritance from a common ancestor that had this peculiarity is more likely, and this is confirmed by other evidence in these languages. Another often repeated example of shared aberrancy is the suppletive agreement between English *good/better/best* and German *gut/besser/best*, where examples such as this are held to have probative value for showing languages are related.

Morphological correspondences of the 'shared aberrancy' type are an important source of evidence for distant genetic relationships.

Borrowing

Diffusion is a source of nongenetic similarity among languages that can complicate evidence for remote relationships. For example, the controversial 'Chibchan-Paezan' hypothesis (grouping several South American language families, part of 'Amerind') has the proposed cognate set 'axe' with words from only four of the many languages involved, but two of these are loans: Cuitlatec *navaxo* 'knife', from Spanish *navajo* 'knife, razor', and Tunebo *baxita* 'machete', from Spanish *machete* (Tunebo has nasal consonants only before nasal vowels, hence *b* substitutes for Spanish *m*) (Greenberg, 1987: 108). When two of the four pieces of evidence are borrowings, the putative 'axe' cognate must be abandoned. Examples

such as this are not uncommon in proposals of distant genetic relationship.

Semantic Constraints

It is dangerous to present phonetically similar forms with different meanings as potential evidence of remote genetic relationship, assuming semantic shifts have taken place. Of course meaning can shift, but in hypotheses of remote relationship the assumed semantic shifts cannot be documented, and the greater the semantic latitude permitted in compared forms, the easier it is to find phonetically similar forms that have no historical connection (as in the Pipil-Finnish examples, above). When semantically nonequivalent forms are compared, chance phonetic similarity is greatly increased. Within families where the languages are known to be related, etymologies are not accepted unless an explicit account of any assumed semantic changes can be provided. The problem of excessive semantic permissiveness is one of the most common and most serious in long-range comparisons, for example, sets cited for Nostratic compare forms meaning 'lip/mushroom/soft outgrowth', 'grow up/become/tree/be', for Amerind hypothesis 'excrement/night/grass', 'child/copulate/son/girl/boy/tender/bear/small'. It is for reasons such as this that these proposals of more remote linguistic relationship are disputed.

Onomatopoeia

Onomatopoetic words imitate the real-world sound associated with their meanings. They may be similar in different languages because they have independently approximated the sounds of nature, not because they share any common history. A way to reduce the sound-imitative problem is to omit from long-range comparisons any word which cross-linguistically frequently has similar imitative form, for example 'blow', 'breathe', 'suck', 'laugh', 'cough', 'sneeze', 'break/cut/chop/split', 'cricket', 'crow' (bird names in general), 'frog/toad', 'lungs', 'baby/infant', 'beat/hit/pound', 'call/shout', 'choke', 'cry', 'drip/drop', 'hiccough', 'kiss', 'shoot', 'snore', 'spit', and 'whistle'. Unfortunately, examples of onomatopoetic words are frequent in proposals of distant genetic relationships.

Nursery Forms

Nursery words (the 'mama-nana-papa-dada-caca' sort) should be avoided, since they typically share a high degree of cross-linguistic similarity that is not due to common ancestry. Nevertheless, examples of nursery words are frequent in cases of long range comparison. The words involved are typically 'mother', 'father', 'grandmother', 'grandfather', and often 'brother', 'sister', 'aunt', and 'uncle', and have shapes like *mama*, *nana*, *papa*, *baba*, *tata*, *dada*. Jakobson (1962[1960]: 542–543) explained the cross-linguistic nongenetic similarity among nursery forms. Nursery words provide no reliable support for genetic relationship.

Short Forms and Unmatched Segments

How long proposed cognates are and the number of matched sounds within them are important, since the greater the number of matching sounds in a proposed cognate set, the less likely it is that accident accounts for the similarity. Monosyllabic words (CV, VC, V) are so short that their similarity to forms in other languages could also easily be due to chance. If only one or two sounds of longer forms are matched, chance may explain the similarity. Such comparisons are not persuasive.

Chance Similarities

Chance (accident) is another possible explanation for similarities in compared languages and needs to be avoided. The potential for accidental matching increases dramatically when one leaves the realm of basic vocabulary, when one increases the pool of words from which potential cognates are sought, and when one permits the semantics of compared forms to vary even slightly (Ringe, 1992: 5).

Cases of similar but noncognate words are well-known, for example French *feu* and German *Feuer* fire', English *much* and Spanish *mucho* 'much'. The phonetic similarity in these basic vocabulary items is due to accidental convergence due to the sound changes that they have undergone, not to inheritance from any common word in the proto language. That originally distinct forms in different languages can become similar due to sound changes is not surprising, since even within a single language originally distinct words can converge due to sound changes, for example, English *lie/lie* (from Proto-Germanic **ligjan* 'to lie, lay'/**leugan* 'to tell a lie').

Sound–Meaning Isomorphism

Only comparisons which involve both sound and meaning together are permitted. Similarities in sound alone (for example, the presence of tones in compared languages) or in meaning alone (for example, grammatical gender in languages compared) are not reliable, since they can develop independently of genetic relationship, due to diffusion, accident, and typological tendencies.

Only Linguistic Evidence

Only linguistic information, no nonlinguistic consideration, is permitted as evidence of distant genetic

relationship. Shared cultural traits, mythology, folklore, technologies, and gene pools must be eliminated from arguments for linguistic relationship. The wisdom of this is seen in face of the many strange proposals based on nonlinguistic evidence. For example, some earlier African classifications proposed that Ari (Omotic) belongs to either Nilo-Saharan or Sudanic 'because the Ari people are Negroes' ('racial' evidence), that Moru and Madi belong to Sudanic because they are located in central Africa (geographical evidence), or that Fula is Hamitic because its speakers herd cattle, are Moslems (cultural evidence), and are tall and Caucasoid (physical attributes) (Fleming, 1987: 207). Clearly the language one speaks does not deterministically depend on one's cultural and biological connections.

Erroneous Morphological Analysis

Where compared words are analyzed with more than one morpheme, it is necessary to show that the segmented morphemes in fact exist in language. Unfortunately, unmotivated morphological divisions are frequent in proposals of remote relationship. Often, a morpheme boundary is inserted where none is justified, as for example, the arbitrarily segmented Tunebo 'machete' as *baxi-ta* (borrowed from Spanish *machete*, and contains no morpheme boundary). This false morphological segmentation falsely makes the Tunebo word appear more similar to the other proposed cognates, Cabecar *bak* and Andaqui *boxo-(ka)* 'axe' (Greenberg, 1987: 108).

Undetected morpheme divisions are also a problem. An example from the Amerind hypothesis compares Tzotzil *ti?il* 'hole' with Lake Miwok *talokh* 'hole', Atakapa *tol* 'anus', Totonac *tan* 'buttocks', Takelma *telkan* 'buttocks' (Greenberg, 1987: 152); however, the Tzotzil form is *ti?-il*, from *ti?* 'mouth' + *-il* 'indefinite possessive suffix', meaning 'edge, border, lips, mouth', but not 'hole'. The appropriate comparison *ti?* 'mouth' bears no particular resemblance to the other forms with which it is compared.

Spurious Forms

Another problem is that of nonexistent or erroneous 'data' from 'bookkeeping' problems and 'scribal' errors. For example, for the Mayan-MixeZoquean hypothesis (Brown and Witkowski, 1979), Mixe-Zoquean words meaning 'shell' were compared with K'iche' (Mayan) *sak'*, said to mean 'lobster', actually 'grasshopper' – a misunderstanding of Spanish *langosta*, which in Guatemala (where K'iche' is spoken) means 'grasshopper', but 'lobster' in other varieties of Spanish. A comparison of 'shell' and 'grasshopper' makes no sense. Errors of this sort can be serious; for example, in the Amerind hypothesis (Greenberg, 1987) none of the words given as Quapaw are in fact from Quapaw; all are from Biloxi and Ofo; none of the words given as Proto-Mayan are from Proto-Mayan, rather from Proto-K'ichean.

Given the disputes about proposed distant genetic relationships, these methodological principles for long-range comparison are extremely important. Research on possible distant genetic relationships that does not conform to these methodological principles and cautions will remain inconclusive.

Some Examples of Long-Range Proposals

It will be instructive to look briefly at some specific proposals to see why most mainstream historical linguists do not accept these hypotheses. (Space does not permit full evaluation, but references are given for more detail.)

Altaic

The Altaic hypothesis would group Turkic, Mongolian, and Tungusic; some versions also include Korean and Japanese. While 'Altaic' is repeated in encyclopedias, most leading 'Altaicists' have abandoned the hypothesis. The most serious problems are the extensive borrowing among the 'Altaic' languages, lack of convincing cognates, lack of basic vocabulary, extensive areal diffusion, problems with the putative sound correspondences, and reliance on typologically commonplace traits. The shared 'Altaic' traits include vowel harmony, relatively simple phoneme inventories, agglutination, suffixing, (S)OV word order (and postpositions), no verb 'to have' for possession, no articles or gender, and nonmain clauses in nonfinite (participial) constructions. However, these shared features are commonplace typological traits, and thus are not good evidence of genetic relationship because they can easily develop independently in unrelated languages. These 'Altlaic' features are also areal traits, shared by a number of languages in surrounding regions, thus perhaps due to diffusion. Similarities in the first and second person pronoun paradigms have impressed proponents of Altaic, although critics point out that pronouns are borrowed far more frequently than proponents acknowledge and pronoun patterns of the type cited for Altaic are also not unusual nor unexpected cross-linguistically. In short, the evidence for genetic relationship has not been persuasive, explaining why so many reject the 'Altaic' hypothesis. (Campbell and Poser, in press.)

Nostratic

The Nostratic hypothesis as advanced in the 1960s by Illich-Svitych would group Indo-European, Uralic,

Altaic, Kartvelian, Dravidian, and Hamito-Semitic [later Afroasiatic], though other versions of the hypothesis would include various other languages. The sheer number of languages and many proposed cognates involved might make it seem difficult to evaluate Nostratic. Nevertheless, assessment is possible. With respect to the many putative cognate sets, assessment can concentrate on those cases considered the strongest by proponents of Nostratic (those of Dolgopolsky, 1986 and Kaiser and Shevoroshkin, 1988). Campbell (1998) shows that these strongest cases do not hold up and that the weaker sets are not persuasive (see below). We can easily determine to what extent the proposed reconstructions correspond to typological expectations, whether the proposed cognates are permissive in semantic associations, and when onomatopoeia, forms too short to deny chance, nursery forms, and the like are involved.

Illich-Svitych's version of Nostratic exhibits the following methodological problems. (See Campbell, 1998, 1999 for details.)

1. Descriptive forms. Illich-Svitych is forthright in labeling 26 of his 378 forms as 'descriptive,' meaning onomatopoetic, affective, or sound-symbolic, i.e., 7% of the total. There are 16 additional onomatopoetic, affective, or sound-symbolic forms, not so labeled, or a total of approximately 11%.
2. Questionable cognates. Illich-Svitych himself indicates that 57 or the 378 sets are questionable (15%), signaled with a question mark. However, this number should be greatly increased, since in numerous forms Illich-Svitych signals problems in other ways, with slanted lines (/ /) for things not conforming to expectation, with question marks, and with upper-case letters in reconstructions to indicate uncertainties or ambiguities.
3. Sets with only two families represented. One of Illich-Svitych's criteria was that only cognate sets with representatives from at least three of the six 'Nostratic' families would be considered as supportive. Nevertheless, 134 of the 378 sets involve forms from only two families (35%), questionable by Illich-Svitychs own criteria.
4. Noncorresponding sound correspondences. Frequently, the forms presented as evidence of Nostratic do not exhibit the proposed sound correspondences, i.e., they have sounds at odds with those that would be required according to the Nostratic correspondence sets. Campbell (1998), looking mostly only at stops and only at the Indo-European and Uralic data, found 25 sets that did not follow the proposed Nostratic correspondences. There is another way in which Illich-Svitych's putative sound correspondences are not consistent with the standard comparative method. Several of the putative Nostratic sounds are not reflected by regular sound correspondences in the languages. For example, "in Kartv[elian] and Indo-European, the reflexes of Nostratic *[**]p* are found to be unstable" (Illich-Svitych, 1990: 168). Nostratic forms beginning in ***p* reveal that both the Indo-European and the Kartvelian forms arbitrarily begin with either **p* or **b*, but this is not regular sound change and is not sanctioned by the comparative method. Similarly, glottalization in Afroasiatic is said to occur "sporadically under other conditions still not clear" (Illich-Svitych, 1990: 168). In the correspondence sets, several of the languages are listed with multiple reflexes of a single Nostratic sound, but with no explanation of conditions under which the distinct reflexes might appear.
5. Short forms. Of Illich-Svitych's 378 forms, 57 (15%) involve short forms (CV, VC, C, or V), incapable of denying chance as an alternative explanation.
6. Semantically nonequivalent forms. Some 55 cases (16%) involve comparisons of forms in the different languages that are fairly distinct semantically.
7. Diffused forms. Given the history of central Eurasia, with much language contact, it is not at all surprising that some forms turn out to be borrowed. Several of the Nostratic cognates have words which have been identified by others as loans, including: 'sister-in-law', 'water', 'do', 'give', 'carry', 'lead', 'to do'/'put', 'husband's sister', to which we can add the following as probable or possible loans: 'conifer, branch, point', 'thorn'; 'poplar'; 'practice witchcraft'; 'deer'; 'vessel'; 'birch'; 'bird cherry'; 'honey', 'mead'; 'poplar'.
8. Typological problems. Nostratic as traditionally reconstructed is typologically flawed. Counter to expectations, few Nostratic roots contain two voiceless stops; glottalized stops are considerably more frequent than their plain counterparts; Nostratic affricates change to a cluster of fricative + stop in Indo-European.
9. Evaluation of the strongest lexical sets. An examination of the Nostratic sets held by proponents to be the strongest reveals serious problems with most. These include Dolgopolsky's (1986) 15 most stable lexemes. Most are questionable in one way or another according to the standard criteria for assessing proposals of remote linguistic kinship. In the Nostratic sets representing Dolgopolsky's 15 most stable glosses, four have problems with phonological correspondences; five

involve excessive semantic difference among the putative cognates; four have representatives in only two of the putative Nostratic families; two involve problems of morphological analysis; Illich-Svitych himself listed one as doubtful; and finally, one reflects the tendency to rely too heavily on Finnish when not supported by the historical evidence. All but two are challenged, and for these two the relevant forms needed for evaluation are not present. (See Campbell, 1998 for details.) These 'strong' cases are certainly not sufficiently robust to encourage faith in the proposed genetic relationship.

Once again, it is for reasons of this sort that most historical linguists reject Nostratic.

Amerind

Greenberg (1987) proposed that all Native American languages, except Na-Dene and Eskimo-Aleut languages, belong to single macro-family, Amerind, based on multilateral comparison (see above). Amerind is rejected by virtually all specialists in Native American languages and by the vast majority of historical linguists. Specialists maintain that valid methods do not at present permit reduction of Native American languages to fewer than about 150 independent language families and isolates. Amerind has been highly criticized on various grounds. There are exceedingly many errors in Greenberg's data: "the number of erroneous forms probably exceeds that of the correct forms" (Adelaar, 1989: 253). Where Greenberg stops – after assembling superficial similarities and declaring them due to common ancestry – is where other linguists begin. Since such similarities can be due to chance, borrowing, onomatopoeia, sound symbolism, nursery words (the *mama, papa, nana, dada, caca* sort), misanalysis, and much more, for a plausible proposal of remote linguistic relationship, one must attempt to eliminate all other possible explanations, leaving a shared common ancestor as the most likely. Greenberg made no attempt to eliminate these other explanations, and the similarities he amassed appear to be due mostly to accident and a combination of these other factors: "I find no evidence whatsoever that [Greenberg's] putative cognate sets . . . represent anything other than chance similarities" (Ringe, 1996: 152). In various instances, Greenberg compared arbitrary segments of words, equated words with very different meanings (for example, 'excrement/night/grass'), misidentified many languages, failed to analyze the morphology of some words and falsely analyzed that of others, neglected regular sound correspondences, failed to eliminate loanwords, and misinterpreted well-established findings. The Amerind 'etymologies' proposed are often limited to a very few languages of the many involved. (For details and examples, see Adelaar, 1989; Berman, 1992; Campbell, 1988, 1997a; Kimball, 1993; McMahon and McMahon, 1995; Poser, 1992; Rankin, 1992; Ringe, 1992, 1996). Finnish, Japanese, Basque, and other randomly chosen languages fit Greenberg's Amerind data as well as or better than any of the American Indian languages do. Greenberg's method has proven incapable of distinguishing implausible relationships from Amerind generally (Campbell, 1988; Campbell, 1997b).

In short, it is with good reason Amerind has been rejected.

Loth, Joseph (1847–1934)

P-Y Lambert, The Sorbonne, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Born in 1847 near Guéméné-sur-Scorff, Loth was a native speaker of Breton Vannetais. After he obtained his Baccalauréat in Vannes 'Grand-Séminaire,' he chose to remain a layman and became a teacher. Some time after the war of 1870, he came to Paris to resume his studies. After earning a diploma at the École des Hautes Études and writing a thesis 'ès lettres' (1884), he was given the post of Lecturer in Greek in Rennes University – where he soon became a professor (1889) and then dean of the arts faculty. In 1886 he founded a scholarly journal, *Annales de Bretagne*, and he lectured on Celtic languages from 1903 on. He succeeded D'Arbois de Jubainville as Professor of Celtic in the Collège de France (1910–1930). He was also a member of the Académie des Inscriptions et Belles-Lettres, and director of the journal *Revue Celtique* when he died in 1934 at the age of 87. His life was extremely productive; he left an important corpus of work and had a formative influence on many pupils.

At the École des Hautes Études, his thesis concerned the British (Brittonic) colonization of Brittany from the 5th to the 7th century: his general theory was mainly in agreement with the ideas of modern historians, such as Arthur de La Borderie: the Bretons were immigrants coming from Great Britain into Armorica. His diploma was a dictionary collecting all the evidence provided by Old Welsh, Old Cornish, and Old Breton glosses. Joseph Loth wanted to make known to every Breton the close kinship of their language with that of the Welsh (he himself had a Welsh wife). For that, he had to teach the history of Breton and he published a selection of Breton texts from different periods, the *Chrestomathie bretonne*. With another book on the Latin borrowings in the Brittonic dialects (1892), he became the foremost authority on the phonetic history of British Celtic.

He published a splendid translation of the Welsh prose tales, *Mabinogion* (1913), and a study of

collection of papers on language change and relationship by Soviet linguists. Ann Arbor: Karoma Publishers. 27–50.

In 1886 he founded a scholarly journal, *Annales de Bretagne*, and he lectured on Celtic languages from 1903 on. He succeeded D'Arbois de Jubainville as Professor of Celtic in the Collège de France (1910–1930). He was also a member of the Académie des Inscriptions et Belles-Lettres, and director of the journal *Revue Celtique* when he died in 1934 at the age of 87. His life was extremely productive; he left an important corpus of work and had a formative influence on many pupils.

At the École des Hautes Études, his thesis concerned the British (Brittonic) colonization of Brittany from the 5th to the 7th century: his general theory was mainly in agreement with the ideas of modern historians, such as Arthur de La Borderie: the Bretons were immigrants coming from Great Britain into Armorica. His diploma was a dictionary collecting all the evidence provided by Old Welsh, Old Cornish, and Old Breton glosses. Joseph Loth wanted to make known to every Breton the close kinship of their language with that of the Welsh (he himself had a Welsh wife). For that, he had to teach the history of Breton and he published a selection of Breton texts from different periods, the *Chrestomathie bretonne*. With another book on the Latin borrowings in the Brittonic dialects (1892), he became the foremost authority on the phonetic history of British Celtic.

He published a splendid translation of the Welsh prose tales, *Mabinogion* (1913), and a study of

Welsh metrics, particularly on the archaic poem of the Black Book of Carmarthen. He also studied aspects of Middle Welsh morphology and syntax (the use of the verbal particle *rhy*, for example). Unfortunately, his contribution to Welsh studies also includes a bitter criticism of the Welsh grammar of John Morris-Jones (Bangor), which created some resentment against him among certain scholars.

He had a sound as well as profound knowledge of the living Celtic languages, in addition to his own Bas-Vannetais dialect, specializing particularly in Celtic lexicography and etymology. This scholar of another age, though less productive than Whitley Stokes (*see* **Stokes, Whitley (1830–1909)**), gives a genuine insight into the Celtic cultures of the past: his philological studies and his etymologies were a means of reviving the past, by discovering the real meaning of older texts and recovering the lost unity of the Celtic languages. As a linguist, he felt obliged to communicate his results to the historians and the archaeologists: he thoroughly studied such semantic fields as names of cereal crops, horses, and sanctuaries. He took a great interest in the newly found Gaulish inscriptions of Coligny (1904) and La Graufesenque (1924). Towards the end of his life, alas, he was very active in defense of the fake inscriptions of Glozel.

Louisiana Creole

T Klingler, Tulane University, New Orleans, LA, USA

© 2006 Elsevier Ltd. All rights reserved.

This French-lexifier creole is spoken by an estimated 10 000–20 000 persons (reliable figures are not available) residing mainly in southwestern Louisiana. Most speakers live along or near the Bayou Teche, especially in the parishes of St. Landry, St. Martin, and Lafayette, but there are also pockets of speakers in several other parishes. Although it is commonly associated with African Americans and Creoles of color, Louisiana Creole (LC) is also the first language of many European Americans. The language has long coexisted with regional varieties of French, often referred to collectively as Cajun, and it is at least in part the continued influence of these varieties that explains why LC is structurally less distant from French than are the French-lexifier creoles of the Caribbean. LC shares a number of important features with Haitian Creole (e.g., the progressive marker *ape*, the verb *gen* 'to have,' and the possessive particle *kèn/tchèn*), and some linguists maintain that LC had as its origin a creole or pre-creole language imported to Louisiana from the French colony of Saint-Domingue before it became the free republic of Haiti. However, evidence that LC's development predated the significant population migration from Saint-Domingue to Louisiana in the early 19th century casts doubt on this claim and strengthens the possibility that LC is indigenous to the region. Today, the future of LC remains uncertain, since most fluent speakers are now elderly and the language is not being passed on to younger generations.

LC varies considerably according to region, ethnic group, and social context. The linguistic situation in Louisiana is often said to form a speech continuum, with the type of LC that is furthest removed from French constituting the basilectal pole, and Cajun or, depending on the model used, Referential French constituting the acrolectal pole. Any given utterance, however, may display a greater or lesser quantity of French-like or Creole-like features, such that it may best be assigned to the broad mesolectal range lying between the two poles of the continuum.

Like the other French-lexifier creoles, LC features definite articles that are postposed to the noun (*tab-la* 'the table,' *chyen-ye* 'the dogs'); a personal pronoun system in which all of the pronouns, regardless of function, are derived from the tonic pronouns of French (1 sg. *mo* < *moi*, 2 sg. *to* < *toi*, 3 sg. *li* < *lui*, etc.); and a verbal system that shows very little inflectional morphology but relies instead on a series of markers placed before the verb to express notions of tense, mood, and aspect. The most important of these are the anterior marker *te*; the progressive

Welsh metrics, particularly on the archaic poem of the Black Book of Carmarthen. He also studied aspects of Middle Welsh morphology and syntax (the use of the verbal particle *rhy*, for example). Unfortunately, his contribution to Welsh studies also includes a bitter criticism of the Welsh grammar of John Morris-Jones (Bangor), which created some resentment against him among certain scholars.

He had a sound as well as profound knowledge of the living Celtic languages, in addition to his own Bas-Vannetais dialect, specializing particularly in Celtic lexicography and etymology. Lounsbury, Floyd Glenn (1914–1998)

W L Chafe, University of California at Santa Barbara, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Floyd Glenn Lounsbury was born in Stevens Point, Wisconsin on April 25, 1914 and died on May 14, 1998 in New Haven, Connecticut. He attended the University of Wisconsin at Madison, majoring in mathematics, and while still an undergraduate he was recruited by the linguist Morris Swadesh to assist in the Oneida Language and Folklore Project funded by the Works Progress Administration (WPA). The goal of that project was to teach young Oneidas to write their language, and then to ask them to record folktales told by older members of the Oneida community. When Swadesh left Wisconsin in 1939, Lounsbury became director of the project. Using an Oneida orthography that he and Swadesh had developed, he oversaw its use in the collection of a variety of Oneida texts, which not only were of value to the Oneida community but also provided Lounsbury with material for an analysis of Oneida phonology and grammar. After WPA funding ended in the summer of 1940, he entered the University of Wisconsin M.A. program and planned to submit a thesis on Oneida phonology. World War II intervened, however, and he was not awarded the M.A. until 1946.

During the war Lounsbury served in the U.S. Army Air Force in Brazil as a meteorologist. At the war's end he turned from meteorology to anthropology, enrolling as a graduate student at Yale University and completing a dissertation on Oneida verb morphology. When he received the Ph.D. in 1949 he was immediately hired by the Yale Department of Anthropology, where he taught from 1949 until his retirement in 1979. During most of that period he was affiliated with the Department of Linguistics as well. He was a Fellow of the Center for Advanced Study in the Behavioral Sciences (1963–1964), and was on two occasions a Senior Research Scholar at Dumbarton Oaks in Washington (1973–1974 and 1977–1978). He was elected to the National Academy of Sciences in 1969, the American Academy of Arts and Sciences in 1976, and the American Philosophical Society in 1987. In 1971 he received the Wilbur Cross Medal from the Yale Graduate School of Arts and Sciences, the school's highest honor to one of its alumni. He was awarded an honorary LL.D. by the University of Pennsylvania in 1987, and was chosen to deliver the Distinguished Lecture at the annual meeting of the American Anthropological Association in 1990. A full bibliography of his work is available in Chafe (1998).

Lounsbury contributed importantly to three distinct fields of research and teaching: the recording and analysis of Iroquoian languages, the study of kinship systems, and the decipherment of Mayan hieroglyphs. In all three of these areas, in addition to his own substantial contributions, he was able to set much of the agenda that was subsequently followed by other researchers, while he recruited a succession of new scholars who continued and refined his work.

The extent of Lounsbury's influence on Iroquoian linguistic scholarship is difficult to exaggerate. When his dissertation was published in 1953 under the title *Oneida verb morphology*, it became the standard on which future studies of Iroquoian languages were based. In it he described the intricate structure of Oneida verbs in a way that had never previously been done for any Iroquoian language, setting forth, for example, the entire inventory of pronominal prefixes and their alternating forms, accounting for aspectual distinctions, and illuminating numerous other areas of Iroquoian linguistic structure. He himself worked to a greater or lesser extent with most of the extant languages in that family, not only with Oneida but also extensively with Mohawk, Cayuga, Tuscarora, and Cherokee. He had a profound

marker *ape* (*e* in Pointe Coupee Parish); the future maker *a*, *va*, or *ale*; and the conditional marker *se*: *Ye te ka lir* 'They could read'; *Lavach-la ape kòmanse dòn dule* 'The cow is beginning to give milk'; *Vou pa kwa l a chinen?* 'Don't you think he'll win?'

A full bibliography of his work is available in Chafe (1998).

Lounsbury contributed importantly to three distinct fields of research and teaching: the recording and analysis of Iroquoian languages, the study of kinship systems, and the decipherment of Mayan hieroglyphs. In all three of these areas, in addition to his own substantial contributions, he was able to set much of the agenda that was subsequently followed by other researchers, while he recruited a succession of new scholars who continued and refined his work.

The extent of Lounsbury's influence on Iroquoian linguistic scholarship is difficult to exaggerate. When his dissertation was published in 1953 under the title *Oneida verb morphology*, it became the standard on which future studies of Iroquoian languages were based. In it he described the intricate structure of Oneida verbs in a way that had never previously been done for any Iroquoian language, setting forth, for example, the entire inventory of pronominal prefixes and their alternating forms, accounting for aspectual distinctions, and illuminating numerous other areas of Iroquoian linguistic structure. He himself worked to a greater or lesser extent with most of the extant languages in that family, not only with Oneida but also extensively with Mohawk, Cayuga, Tuscarora, and Cherokee. He had a profound

influence on the career paths of a number of others whose work with Iroquoian languages followed his example.

Although he had been trained in the tradition of American structural linguistics established by Leonard Bloomfield and others, Lounsbury had a special interest in semantics, an area that had been neglected within that tradition. He recognized the potential offered by the kinship vocabularies of diverse languages as a way of extending structuralist methods to meanings. In an elegant fashion he analyzed kinship systems in terms of semantic 'components,' showing that a small number of components and rules for their combination could account for a variety of structurally different systems. Between 1956 and 1968 he published five seminal articles on kinship analysis involving the Pawnee, Seneca, Crow, and Omaha (Omaha-Ponca) languages, the language of the Trobriand Islands, and early Latin. His writings attracted widespread attention, as linguists and anthropologists saw in them evidence that at least some areas of meaning could be as systematically analyzed as phonology and grammar. It would be irresponsible today to undertake a study of a kinship system without taking Lounsbury's work into account.

By the 1950s Lounsbury had developed an interest in Mayan hieroglyphs, and he gradually devoted more and more time to them. The nature of Mayan writing was poorly understood when he began, and he became a principal advocate of phonetic interpretation of the glyphs, establishing himself as a pioneer in Mayan decipherment. During the 1970s and 1980s his publications were instrumental in converting Mayan hieroglyph studies into a major field of research. He was able to set forth clear principles for the discovery and demonstration of the values of the glyphs, but even while the principles of phonological representation were being established and a significant selection of Mayan texts being read, he turned his attention to grammatical analysis of those texts, demonstrating the dependence of hieroglyph studies on a detailed understanding of Mayan linguistics. Most Mayan decipherment was based on the analysis of calendrical patterns of a sort that appealed to his mathematical bent. He continued to work on Mayan mathematics throughout the 1980s, extending his work to the investigation of astronomical knowledge, its calendrical structure, and cultural uses reflected in hieroglyphic texts.

After an extended period during which he devoted much of his time first to kinship and then to Mayan hieroglyphs, in the 1990s Lounsbury returned to Iroquoian research, working on, among other things, the interpretation of an important Oneida text that he had recorded earlier. In the last years of his life he continued to participate actively in conferences on both Iroquoian and Mayan topics.

Lowth, Robert (1710–1787)

K Navest, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

It is for his *Short introduction to English grammar*, published anonymously in 1762 by Andrew Millar and Robert and James Dodsley, that Lowth is best known among linguists today. It is a normative grammar, and Lowth's approach is evident in the numerous footnotes in which he quotes "the best Authors" breaking the rules he is describing.

Because of its popularity, Lowth's grammar was reprinted at least 30 times during the author's lifetime and 17 times after his death. It was even translated into German.

Lowth was born in Winchester on November 27, 1710. In 1722 he was admitted as a scholar at Winchester College. In 1729 Lowth entered New College, Oxford, where he was Professor of Poetry from 1741 until 1752. In 1752, Lowth married Mary Jackson. They had seven children of which only two outlived their father. In 1753, Lowth's Latin lectures were published as *De sacra poesi Hebraeorum praelectiones*. Five years later, Lowth published *The life of William of Wykeham*, a biography about the founder of Winchester College and New College. Lowth's knowledge of Hebrew led him to translate the book of Isaiah in 1778. In 1766, Lowth became Bishop of St. David's, and only a few months later Bishop of Oxford. In 1777, he was made Bishop of London, which he remained until his death.

Lowth originally wrote his grammar for his eldest son Thomas Henry (1753–1778), because he felt that there was a need for an English grammar that could prepare children for the study of Latin. *A short introduction to English grammar* contains several references to Lowth's son in the form of examples such as "Thomas's book" and "Thomas is loved by me." Lowth appears to have begun the grammar in the autumn of 1757 when his son was only 4 years old. When he told his friend, the Chancellor of the Exchequer, Henry Bilson Legge (1708–1764), about his project, Legge asked for a copy of the grammar for his own son, leading Lowth to publish his grammar. Lowth may have intended his grammar as a children's grammar, but many people considered it too difficult for young learners. Daniel Fenning (1771) admired Lowth's section on syntax in which Lowth divides the sentence into twelve types of 'phrase,' but thought that the grammar was more suitable "for Men of Letters than for Youth at school." It was probably Lowth's publisher Robert Dodsley (1703–1764), who had also been behind the publication of Johnson's *Dictionary* (1755), who decided to make Lowth's grammar available to a wider public.

Lu Fa-yan (fl. 600 A.D.)

B-C Kwok, Hong Kong, China

© 2006 Elsevier Ltd. All rights reserved.

Lu Fayan is generally remembered as the compiler of the Chinese rhyme dictionary *Qieyun*. We do not know much about his life. The biography of his father Lu Shuan (ca. 539–591) is included in *Sui Shu* (The book of the Sui dynasty), in which we learn that the Lu family was native to Linzhang in northern China.

Qieyun was revised and extended by scholars of the Tang (618–907) and the Song (960–1279) dynasties, and eventually several versions were produced. Of these, *Guangyun* (dated 1007–1008) has gained greatest popularity. We generally regard the phonological system reflected in these dictionaries as Middle Chinese or Ancient Chinese.

The original version of *Qieyun* is now no longer extant, but its preface, written by Lu himself in 601, is still available. That writing, with slightly more than 400 words, described the background of the compilation and the peculiarities of the dialects at that time, but more important is that it provided some hints uncovering the nature of *Qieyun*. Speaking of the meeting with eight colleagues 20 years earlier that had led to the writing of the book, Lu wrote, "We discussed the right and the wrong of South and North, and the prevailing and the obsolete of past and present" (adapted from Malmqvist, 1968). By consulting various contemporary documents, especially the *Yanshi jiaxun* (The family instructions of the Yan clan), we are confident in claiming that the terms 'South' and 'North' that appear in the preface refer to the cities of Jinling (today Nanjing) and

Lu Fayan is generally remembered as the compiler of the Chinese rhyme dictionary *Qieyun*. We do not know much about his life. The biography of his father Lu Shuan (ca. 539–591) is included in *Sui Shu* (The book of the Sui dynasty), in which we learn that the Lu family was native to Linzhang in northern China.

Qieyun was revised and extended by scholars of the Tang (618–907) and the Song (960–1279) dynasties, and eventually several versions were produced. Of these, *Guangyun* (dated 1007–1008) has gained greatest popularity. We generally regard the phonological system reflected in these dictionaries as Middle Chinese or Ancient Chinese.

The original version of *Qieyun* is now no longer extant, but its preface, written by Lu himself in 601, is still available. That writing, with slightly more than 400 words, described the background of the compilation and the peculiarities of the dialects at that time, but more important is that it provided some hints uncovering the nature of *Qieyun*. Speaking of the meeting with eight colleagues 20 years earlier that had led to the writing of the book, Lu wrote, "We discussed the right and the wrong of South and North, and the prevailing and the obsolete of past and present" (adapted from Malmqvist, 1968). By consulting various contemporary documents, especially the *Yanshi jiaxun* (The family instructions of the Yan clan), we are confident in claiming that the terms 'South' and 'North' that appear in the preface refer to the cities of Jinling (today Nanjing) and

Luoyang, respectively. The phonological systems of the dialects of these two cities were important bases for Lu to establish the framework of *Qieyun*. It is noteworthy that Lu had mentioned the names of the eight other people involved in the earlier discussions of the rhyme dictionary. Three of them came from Jinling, and the remainder from Ye, a city not far away from Luoyang. Lu also placed great importance on earlier sources. It is evident that Lu tried to integrate these materials into his system, while rhyming distinctions in any one of them were mostly maintained. Obviously, *Qieyun* is composite in nature rather than simply a rhyme dictionary based on a single dialect at a certain time. Those who wish to reconstruct the phonetic values of *Qieyun* should first identify its heterogeneous elements.

The aim of the compilation of *Qieyun*, according to the preface, was to promote poetry writing. The language embodied in the dictionary, therefore, cannot be treated as representative of real speech. Lu's main concern was with rhyming practice, not linguistic analysis of the materials he was dealing with. On the other hand, there is not even a single word telling us that Lu had an intention to establish standards of pronunciation through the compilation of the book. This point is often misinterpreted by modern scholars.

By and large, in understanding the development of Chinese languages, *Qieyun* is of paramount importance: it bridged the gap between Old Chinese and the Modern Chinese. It is Lu's contribution to better knowledge of Ancient Chinese phonology.

Luganda (Ganda), a Bantu language of Uganda, is the mother tongue of 3 015 980 speakers (a little more than 16% of the population of Uganda); with an additional 1 million second language speakers, Luganda is the most widely spoken language in Uganda. It belongs to the Narrow Bantu subgroup of the Bantu sub-branch of the Benue-Congo branch of Niger-Congo. It is classified as Zone J15 in Guthrie's classification system for Bantu.

Basic Phonology and Orthography

The Luganda orthography is essentially phonemic. The consonants and vowel phonemes are listed in **Tables 1** and **2**, respectively. IPA symbols corresponding to the

Table 1 Consonants

Luganda

F Katamba, Lancaster University, Lancaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Location and Genetic Affiliation

Luganda (Ganda), a Bantu language of Uganda, is the mother tongue of 3 015 980 speakers (a little more than 16% of the population of Uganda); with an additional 1 million second language speakers, Luganda is the most widely spoken language in Uganda. It belongs to the Narrow Bantu subgroup of the Bantu sub-branch of the Benue-Congo branch of Niger-Congo. It is classified as Zone J15 in Guthrie's classification system for Bantu.

Basic Phonology and Orthography

The Luganda orthography is essentially phonemic. The consonants and vowel phonemes are listed in Tables 1 and 2, respectively. IPA symbols corresponding to the

Table 1 Consonants

Consonant	*Bilabial*	*Labiodental*	*Alveolar*	*Palatal*	*Velar*	*Labiovelar*
Stops						
Voiceless	p		t	c	k	
Voiced	b		d	j [ɟ]	g	
Fricatives						
Voiceless		f	s			
Voiced		v	z			
Nasals	m		n	ny [ɲ]	ng [ŋ]	
Approximants			l[a]	y (j)		w

[a]Though [l] and [r] are allophones of the phoneme /l/, they are represented by separate letters in the orthography. The letter 'r' is used after front vowels and 'l' is used elsewhere.

standard letters are shown in brackets for palatal and velar consonants. As seen in Example (1), gemination (indicated by double letters) is phonemic for both consonants (C) and vowels (V). The typical syllable is CV or CVV. The only consonant clusters allowed are NC (i.e., nasal + consonant), as in *nkola*, and for consonant plus glide, as in *mukwano* 'friendship':

(1) ogula 'we buy' oggula 'you open'
nkola 'I work' nkoola 'I weed'

Tone is phonemic. However, it is not marked in the standard orthography, and that convention is followed here except when tone is being discussed.

On the surface, there is a contrast between low (L) tone, which is unmarked, high (H) (') tone, and falling (HL) (∧) tone. There are no rising tones.

(2) ki sa ni ri zo (L L L L L) 'comb'
ku wó la (L H L) 'to become cool'
ku wólá (L H H) 'to lend money'
bi táà (L HL) 'gourds'

Basic Morphology

Luganda has rich, agglutinative morphology. The typical noun has the following structure (PP = pre-prefix; CP = class prefix):

(3) PP CP ROOT
o- mu- wala 'girl'

The 21 noun classes, each one of them marked by a prefix, are normally paired for singular and plural, as in Example (4):

(4)

	CLASS	PP	CP	STEM	
Singular:	1	o-	mu-	wala	'girl'
	7	e-	ki-	bira	'forest'
Plural:	2	a-	ba-	wala	'girls'
	8	e-	bi-	bira	'forests'

The noun class numbering system is standardized for all Bantu languages.

There is concord in a noun phrase between a noun and any dependent adjectives and determiners:

(5a) o- mu- wala o- no o- mu- nene
PP CP1 girl CP1 this PP CP1 big
'this big girl'

Table 2 Vowels

Vowel	*Front*	*Central*	*Back and round*
High	i		u
Mid	e		o
Low		a	

(5b) e- ki- bira ki- no e- ki- nene
PP CP7 girl CP7 this PP CP7 big
'this big forest'

As seen in Example (6), verbs, compared to nouns, are morphologically more complex (NEG, negation; SM, subject marker; TM, tense marker; FUT, future; OM, object marker; ES, extension suffix; APPL, applicative; FV, final vowel):

(6) te- ba- li- ki- n- deet- er- a
NEG SM TM(FUT) OM1 OM2 bring ES (APPL) FV
not they future it me bring for FV
'They will not bring it for me.'

There is also an elaborate tense/aspect system, with distinct negative and positive paradigms:

(7)

Tense/aspect	**Positive**	**Negative**
Past:	nnalaba	saalaba
Near past:	nnalabye	saalabye
Immediate past:	ndabye	sirabye
Present:	ndaba	siraba
Near future:	nnaasoma	siisome
General future:	ndiraba	siriraba

Basic Syntax

The basic word order in unmarked declarative sentences is subject-verb-object:

(8a) a- ba- wala ba- a- lab- a e- m- bwa
PP- CP2- girl CP2- PAST- see- FV PP- CP9- dog
'The girls saw the dog.'

(8b) e- m- bwa y- a- lab- a a- ba- wala
PP- CP9- dog CP9- PAST- see- FV PP- CP2- girl
'The dog saw the girls.'

Typically, the head precedes its modifier: e.g., in noun phrases, nouns precede determiners and adjectives (see Examples (5a) and (5b)).

Niklas Luhmann, founder of sociological systems theory, is known within linguistics for the central role of communication within his theory. Within Luhmann's framework, modern society becomes a complex system of communications, with communication serving as a system's basic element and a means of maintaining its distinction from its environment. For Luhmann, communication is a synthesis between information (selection from various referential meanings), utterance (selection from various intentional acts), and understanding (observations of difference between utterance and information).

Luhmann was born December 8, 1927 in Lüneburg, Germany. At age 17, he served in the Luftwaffe and was captured by Americans. After graduating from the University of Freiburg in 1949, he worked in public administration at Lüneburg Administrative Court, developing a file-card system, then at the Ministry of Education of Lower Saxony, working on war reparations. His free time was spent reading Descartes and Kant, among others. In 1960, he married Ursula von Walter, with whom he had three children. In 1961, Luhmann left public administration to study the sociology of Talcott Parsons, a leading systems theorist, at Harvard. Developing his own systems theory, Luhmann taught at Hochschule für Verwaltungswissenschaften in Speyer from 1962 to 1965, before being offered a position at the Sozialforschungsstelle of the University of Münster. In 1966, after two of his earlier works were accepted as thesis and habilitation, Luhmann earned the title of professor. He first lectured at the University of Frankfurt and was appointed full professor of sociology at the newly founded University of Bielefeld, where he served until 1993.

Luhmann, a controversial figure in sociology, particularly for his antihumanistic views, defined a system as a boundary between itself and its complex exterior, or environment. Communication enacted the boundary, by selecting and processing a finite amount of information based on meaning (*Sinn*), the unity of difference between actuality and potentiality, and thereby reducing complexity. Communication also allowed systems to continually reproduce themselves from previously selected elements via a process termed 'autopoiesis,' a term borrowed from cognitive biologists Humberto Maturana and Francisco Varela, meaning self-creation. Social systems are autopoietically closed in that their operation is not determined from the outside. Instead, environmental resources must first be appropriated before contributing to the system's reproduction. Communication based on a unique binary code (i.e., *legal/illegal*) about the system and the environment allows such contact. Social and conscious systems, which were for Luhmann distinct systems, each work according to their own code. Language, one interface between these two distinct systems, is a medium that involves verbal or nonverbal signs that regulate the difference between information and utterance via a process of symbolic generalization.

Luhmann detailed his theory in more than three dozen books, dealing with such diverse subjects as mass media, law, and love. *Social systems* (1995) was considered to be the introduction to his theory. His 2-volume magnum opus *Die Gesellschaft der Gesellschaft* appeared in 1997. Also of note was *Theorie der Gesellschaft oder sozialtechnologie. Was leistet die Systemforschung?* ('Theory of society or social technology: what does systems research accomplish?' Habermas and Luhmann, 1971), a joint publication with critical theorist Jürgen Habermas of the Frankfurt School of Sociology, of which more than 35 000 copies sold in a few years. In addition, works such as Rasch (2000) and Harrison (1995) provided introductions to Luhmann's theory.

Luhmann died November 6, 1998, but not before adding substantially to the fields of linguistics and sociology, particularly as studied in Germany, Japan, and Eastern Europe.

Luhmann is also remembered by his appearance as a character in Paul Wühr's *Das falsche Buch*, together with Ulrich Sonnemann, Johann Georg Hamann, and Richard Buckminster Fuller.

Luick, Karl (1865–1935)

W Viereck, University of Bamberg, Bamberg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Karl Luick was born in Floridsdorf near Vienna in 1865. He studied English, French, and German at the University of Vienna, where he received his Ph.D. in 1888. His Habilitation (D.Litt.) followed only two years later. In 1893, he became the first Professor of English Philology at the University of Graz. He remained there until 1908, when he returned to Vienna. From 1925 to 1926 he was Rektor (President) of the University of Vienna; in 1935 he retired from his chair, dying in the same year.

Luick published widely both in linguistics and in literature, as was customary then (his bibliography in Kastovsky *et al.*, 1988 comprises 223 items). Although he also wrote a *Deutsche Lautlehre* (1904) that came out in three editions, he is best known for his diachronic work on the English language. His major works are *Untersuchungen zur englischen Lautgeschichte* (1896), *Studien zur englischen Lautgeschichte* (1903), and *Historische Grammatik der englischen Sprache* (1914–1940), of which the pages 797–1149 on consonantism were edited by Friedrich Wild and Herbert Koziol and published posthumously. Luick's historical grammar is a presentation of the history of English sounds from Indo-European times down to the 19th century. He had originally also planned volumes on the history of word forms and on the history of constructions, but these remained unwritten. As a Neogrammarian at heart, he was pleased about the regularity with which sound laws work. However, in his book of 1896, he had already begun formulating structuralist thoughts, recognizing the functional load of a linguistic element, the essence of the phoneme, and the concept of minimal pairs.

The structuralist thought of the 'sound system,' with its stress on the proximity or distance of a single sound to or from its neighboring sounds, led Luick to a reinterpretation of the English Great Vowel Shift that operated on long vowels from the 15th to the 17th century, namely, as a 'push-chain' or 'displacement' theory, as opposed to the 'drag-chain' theory advocated by Jespersen in 1909. Luick also proposed a new explanation for the lengthening of Middle English short high vowels in open syllables, according to which they were first lowered and then lengthened. It must be stressed that Luick never started from a uniform, idealized pronunciation but always took the whole spectrum of dialectal variation into consideration. In fact, he was one of the first to have done this.

Lukas, Johannes (1901–1980)

E Shay, University of Colorado, Boulder, CO, USA

© 2006 Elsevier Ltd. All rights reserved.

Johannes Lukas was born on October 7, 1901, in Fischern bei Karlsbad (Karlovy Vary), Bohemia. He attended the University of Vienna, studying Egyptology and African and Oriental languages and culture, while also studying piano at the Vienna Conservatory. Among his professors was Eyptologist and Africanist Wilhelm Czermak. Lukas obtained a doctorate in African languages in 1925. After three years as assistant at the Vienna Museum für Völkerkunde (Ethnology), he spent two years as a tutor at Al-Azhar University. Here he became acquainted with many students from Central African countries, some of whom became Lukas's informants in the first scientific studies of their native languages.

In 1932–1933, as a research fellow of the International African Institute (London), Lukas conducted fieldwork on Kanuri (Saharan), and in 1937 published the seminal grammatical work on that language. After a brief stay at the School of Oriental and African Studies (SOAS) in London, he was accepted in 1934 into the Department of African Studies at the University of Hamburg. Here he taught under Africanist Carl Meinhof, while conducting his postdoctoral (Habilitation) studies and beginning to put into writing his findings on the Saharan and Chadic languages of the Lake Chad area. Lukas's linguistic studies were interrupted by his wartime service, which he spent in Berlin at the Auslands-Hochschule (Foreign University). He resumed teaching in Hamburg and in 1954 succeeded August Klingenheben as Director of the Department of African Studies (now the Institut für Afrikanisitik und Äthiopistik). He held this position until his retirement in 1970.

The languages of the Lake Chad area were Lukas's primary research interest throughout his career. An early project was to compile and analyze linguistic data collected by 19th century traveler Gustav Nachtigal. In 1936, he proposed the Chado-Hamitic (now Chadic, with some alterations) language family as a member of the Hamito-Semitic (Afroasiatic) phylum, and in 1951 he proposed the existence of the East Saharan family (now Saharan). From 1952–1973, Lukas devoted lengthy field trips to conducting the first modern linguistic studies of many languages of the Chadic and Saharan families. Among these are Kanuri (Central Kanuri) and Tubu (Tedaga), both Saharan, and the Chadic languages Bole (Bolanci), Bade, Musgu, Logone (Lagwan), Mokolo, Buduma, and Giziga (North and South). On these he wrote numerous groundbreaking descriptive and comparative works. In the 1960s, he brought particular attention to tone in African languages, a field about which much remains to be discovered. Lukas continued to study and write on African languages well after his retirement in 1970. He died on August 4, 1980, in Hamburg.

Luo

G J Dimmendaal, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

One of the major Nilotic (Nilo-Saharan) languages in terms of number of speakers, Luo (also known as Nilotic Kavirondo), is spoken by approximately 3.5 million people mainly in western Kenya, northern Tanzania, and eastern Uganda. Together with Acholi, Adhola, Alur, Kumam, and Lango, Luo forms the Southern Lwoo cluster within the Western Nilotic branch of Nilotic. The Luo orthography was developed at the beginning of the 20th century. There is a growing body of literature in this Nilotic language, which is also used in the educational system in Kenya.

Luo is among the few Nilotic languages that has also been studied in detail by native speakers, e.g., Okoth-Okombo (1982) and Omondi (1982). One of the pioneers of African linguistics, Archibald Tucker, also produced a grammar of Luo, published posthumously as Tucker (1994). As shown in these studies, Luo has a classical two-tone system with downdrift, downstep, as well as upstep. As is

common in a wide range of languages ranging from Senegal to Ethiopia, it also has vowel harmony based on the position of the tongue root. Luo appears to have retained relatively few prototypical Nilotic features at the morphosyntactic level, presumably as a result of contact with Niger-Congo languages at different periods in time. One stratum, which seems to have affected all Southern Lwoo languages, appears to be due to contact with Ubanguian (Niger-Congo) languages. Another, more recent stratum resulted from intensive contact between Luo and neighboring Bantu (Niger-Congo) languages (cf. Rottland and Okoth-Okombo, 1986; Dimmendaal, 2001; and Storch, 2003).

One manifestation of the intensive lexical and structural borrowing from Bantu is the development of noun class prefixes in Luo. In addition to borrowed prefixes, one finds prefixes that developed from nominal roots, as in *dhó-lúô* 'the Luo language' (from *dhok* 'mouth'); *jà-lúô/jò-lúô* 'Luo person (sg/pl)' from *jal* (sg), *jol* (pl) 'guest, stranger'.

The common constituent order in Luo is SVO. Other members of the Lwoo cluster, such as Anywa or Päri, allow for OVS order and they inflect postverbal subjects with (ergative) case. Luo does not have case marking. Consequently, although VS order may be used in Luo to express presentative focus with intransitive predicates, the postverbal subject is not inflected for case. Compared again to Anywa and Päri, Luo has a reduced system of verbal derivation, using prepositions instead to modify the valency of verbs. On the other hand, Luo developed tense marking on the verb, parallel to neighboring Bantu languages.

Luria, Aleksandr Romanovich (1902–1977)

S A Romashko, Moscow, Russia

© 2006 Elsevier Ltd. All rights reserved.

Born in Kazan, Luria studied medicine and social sciences at the University of Kazan. His early interest in psychology was stimulated mainly by German neo-Kantian philosophy and philosophical hermeneutics (Dilthey) and psychoanalysis (in 1922, he founded a psychoanalytic association in Kazan), as well as by the reflexology of V. Bexterev. In 1923 he was invited to join the activities of the Institute of Psychology in Moscow. In 1924 Luria met L. S. Vygotskiĭ; he worked with him and under his decisive influence for the next 10 years, until Vygotskiĭ's death in 1934. With Vygotskiĭ, Luria took part in the founding of the so-called 'cultural-historical school' in psychology. Referring to ideas of Marxist philosophy, Vygotskiĭ and his school tried to establish objective foundations of the human mind and considered the sociocultural environment as a necessary condition of human psychic activity. The role of language in human phylogeny and ontogeny was crucial for Vygotskiĭ: Language (as a universal tool) was considered to be a main condition of human behavior and thinking. The ideas of the cultural-historical school were elaborated in a critical dialogue with the ideas of K. Bühler and J. Piaget. One of Luria's first projects was the examination of children's linguistic reactions (Luria, 1927).

In a collaborative work with Vygotskiĭ, Luria discussed the behavioral patterns of a 'primitive' mind (child, uneducated person) (Luria and Vygotskiĭ, 1930). Political repression (Luria had to abandon his fieldwork in Central Asia) and Vygotskiĭ's early death interrupted the development of cultural-historical psychology.

Luria then tended to work in more 'neutral' fields: clinical research in neurophysiology (he even obtained an additional degree in medicine in the 1930s) and

common in a wide range of languages ranging from Senegal to Ethiopia, it also has vowel harmony based on the position of the tongue root. Luo appears to have retained relatively few prototypical Nilotic features at the morphosyntactic level, presumably as a result of contact with Niger-Congo languages at different periods in time. Born in Kazan, Luria studied medicine and social sciences at the University of Kazan. His early interest in psychology was stimulated mainly by German neo-Kantian philosophy and philosophical hermeneutics (Dilthey) and psychoanalysis (in 1922, he founded a psychoanalytic association in Kazan), as well as by the reflexology of V. Bexterev. In 1923 he was invited to join the activities of the Institute of Psychology in Moscow. In 1924 Luria met L. S. Vygotskiĭ; he worked with him and under his decisive influence for the next 10 years, until Vygotskiĭ's death in 1934. With Vygotskiĭ, Luria took part in the founding of the so-called 'cultural-historical school' in psychology. Referring to ideas of Marxist philosophy, Vygotskiĭ and his school tried to establish objective foundations of the human mind and considered the sociocultural environment as a necessary condition of human psychic activity. The role of language in human phylogeny and ontogeny was crucial for Vygotskiĭ: Language (as a universal tool) was considered to be a main condition of human behavior and thinking. The ideas of the cultural-historical school were elaborated in a critical dialogue with the ideas of K. Bühler and J. Piaget. One of Luria's first projects was the examination of children's linguistic reactions (Luria, 1927).

In a collaborative work with Vygotskiĭ, Luria discussed the behavioral patterns of a 'primitive' mind (child, uneducated person) (Luria and Vygotskiĭ, 1930). Political repression (Luria had to abandon his fieldwork in Central Asia) and Vygotskiĭ's early death interrupted the development of cultural-historical psychology.

Luria then tended to work in more 'neutral' fields: clinical research in neurophysiology (he even obtained an additional degree in medicine in the 1930s) and

education. Still pursuing his interest in language and linguistic behavior, Luria provided a neurophysiological conception of aphasia. This pioneer work was intensified in the context of World War II, when Luria was treating wounded persons with brain injuries and various kinds of speech disorders (Luria, 1947). This experience became the foundation for Luria's 'neuropsychology,' a discipline combining neurophysiological data with psychological functional analysis. After a hard period of postwar repressions, Luria was able to resume his investigations in the post-Stalinist years. He continued his clinical and educational activities, working at the same time at Moscow State University.

Developing the view of language as a tool and regulator (Luria, 1961), he provided the first outlines of neurolinguistics (Luria, 1975). Luria combined in his neurolinguistic research the structuralist ideas of R. Jakobson and N. Troubetzkoy (paradigmatics and syntagmatics, distinctive features) and generative linguistics with the methods of neuropsychology and neurophysiology.

Evaluating Martin Luther's (**Figure 1**) role in the development of German numbers among the recurrent challenges undertaken by language historians. Among 18th- and 19th-century academics, there was a firm consensus in most quarters that Luther was indeed the 'Father of the German language.' Such a judgment was colored by confessional interests that were seen promoting the notion of Standard German as 'a Protestant language,' a label which, depending on the context, could be either praise or vilification. More recently, the issue has been gradually de-confessionalized. While the assertion of his linguistic paternity of Standard German is untenable, what and how Luther wrote still earns him a place among the most important masters of the German language. His writings – in particular his translation of the Bible – had tremendous influence on how German was spoken and written. This article will touch on three areas: (1) his vernacular literary output, most importantly his translation of the New Testament; (2) his vernacular, its sources and impact; and (3) a summary evaluation of the relation of Luther's German to contemporaneous German languages.

Luther was educated at schools in Magdeburg and Eisenbach and studied the arts at the University of Erfurt. He lectured first on moral philosophy and later on sacred scripture at the University of Wittenberg. A short list of Luther's vernacular writings includes theological treatises, biblical commentaries, sermons, polemical tracts, correspondence, hymn texts, and *Table Talk* – transcribed, revised, and published conversations between Luther and his dinner guests, distributed as devotional reading. It also includes his translations of books of the Bible. His facility in Greek and Hebrew, acquired through private study and tutorial, were commendable by the standards of the day. His translation of the New Testament occurred with the assistance of Philip Melanchton, a professor of Greek at Erfurt, and

education. Still pursuing his interest in language and linguistic behavior, Luria provided a neurophysiological conception of aphasia. This pioneer work was intensified in the context of World War II, when Luria was treating wounded persons with brain injuries and various kinds of speech disorders (Luria, 1947). This experience became the foundation for Luria's 'neuropsychology,' a discipline combining neurophysiological data with psychological functional analysis. After a hard period of postwar repressions, Luria was able to resume his investigations in the post-Stalinist years. He continued his clinical and educational activities, working at the same time at Moscow State University.

Developing the view of language as a tool and regulator (Luria, 1961), he provided the first outlines of neurolinguistics (Luria, 1975). Luria combined in his neurolinguistic research the structuralist ideas of R. Jakobson and N. Troubetzkoy (paradigmatics and syntagmatics, distinctive features) and generative linguistics with the methods of neuropsychology and neurophysiology.

Evaluating Martin Luther's (Figure 1) role in the development of German numbers among the recurrent challenges undertaken by language historians. Among 18th- and 19th-century academics, there was a firm consensus in most quarters that Luther was indeed the 'Father of the German language.' Such a judgment was colored by confessional interests that were seen promoting the notion of Standard German as 'a Protestant language,' a label which, depending on the context, could be either praise or vilification. More recently, the issue has been gradually de-confessionalized. While the assertion of his linguistic paternity of Standard German is untenable, what and how Luther wrote still earns him a place among the most important masters of the German language. His writings – in particular his translation of the Bible – had tremendous influence on how German was spoken and written. This article will touch on three areas: (1) his vernacular literary output, most importantly his translation of the New Testament; (2) his vernacular, its sources and impact; and (3) a summary evaluation of the relation of Luther's German to contemporaneous German languages.

Luther was educated at schools in Magdeburg and Eisenbach and studied the arts at the University of Erfurt. He lectured first on moral philosophy and later on sacred scripture at the University of Wittenberg. A short list of Luther's vernacular writings includes theological treatises, biblical commentaries, sermons, polemical tracts, correspondence, hymn texts, and *Table Talk* – transcribed, revised, and published conversations between Luther and his dinner guests, distributed as devotional reading. It also includes his translations of books of the Bible. His facility in Greek and Hebrew, acquired through private study and tutorial, were commendable by the standards of the day. His translation of the New Testament occurred with the assistance of Philip Melanchton, a professor of Greek at Erfurt, and

Figure 1 Martin Luther.

others, using Erasmus's Greek-Latin edition (1516), the so-called *textus receptus*. This German New Testament was published in 1522. Translation of the Old Testament proceeded at a slower pace. The Pentateuch was published in 1523; and the Psalter, in 1524. It was not until 1534 that Luther published an entire Bible (including a translation of the Greek Old Testament deuterocanonical literature).

Luther's interest in translating the Bible into the vernacular from the sacred languages points immediately to the scholarly movement that provided him with the tools to do just that: Renaissance humanism. This movement originated in Italy but spread to Germany in the last quarter of the 15th century. Humanism had significant impact on the study of languages, ancient and vernacular. Although many Renaissance humanists sided with Luther during the religious controversies of the 16th century, Luther himself cannot be judged a humanist. However, his efforts at translating the Bible into the vernacular, among other projects, made him their beneficiary and sometime ally inasmuch as both he and they were attracted to Hebrew and Greek. Both were also critical of the medieval Latin used in theology and of the accuracy of the Vulgate, the canonical Latin translation of the Bible in use at the time. Because the humanists had for some decades developed and encouraged the study of Greek and Hebrew (*see* **Reuchlin, Johann (1455–1522)**), Luther had the tools at his disposal to learn the languages, to critique the Vulgate itself, and to develop a new understanding of why and how to read the Bible that would be a central tenet of the Reformation in Germany. The principle that church authority and Christian truth were founded *sola scriptura,* on the Bible alone, made Holy Writ's availability through a vernacular translation not just a matter of convenience, but of life and death.

But this would be a translation into what sort of German? Luther's significance for the history of the German language rests in largest part on the German into which he translated the Bible. His education across various dialectic divides in Germany inspired him to apply a widely understandable German he could find. He began with a German from close to home, namely that used in the Meissen court of the electors of Saxony. Meissen is not far from where Luther was born and reared; the Saxon elector Frederick was among Luther's staunchest princely supporters. Nonetheless, this language could only serve as Luther's starting point in that it was a language developed by lawyers and scribes for their professional work and was thus not entirely suitable for capturing the breadth and flavor of biblical and theological expression. Luther was fortunately able to turn to the vernacular theological and mystical texts of several late medieval German writers, who, beginning with Meister Eckhart (ca. 1260–1327/28), had contributed to making the German vernacular more theologically sophisticated. None of this reliance, however, should distract one from Luther's own genius. He was a master of the German language; his own writing and translating is marked with passion and precision.

At the same time, he could not transcend all linguistic divisions in the empire: for example, into the 17th century, Luther's Bible was itself translated into Low German for Protestant populations in the north that found the Saxon tendencies of the vocabulary foreign. His translating did occasion some controversy, in part due to the day's religious disputes, but also touching upon serious questions concerning the translator's art. Accused of both clumsy literalism and tendentious paraphrasing, Luther responded to his critics in 1530 with a treatise on translating (*Ein Sendbrief vom Dolmetschen*). In it Luther argued that good scriptural translating must be inspired by faith itself. The translator must adhere to the original texts, but without depriving the vernacular of its natural cadence and melody. These principles of translation helped him explain his insertion of the word *allein* into Romans 3:28, resulting in the human person's theological justification "by faith *alone*." It also explained why in the angelic salutation (Luke 1:28) he used *Holdselige* in reference to Mary instead of *voll Gnade,* the latter being a more common German rendering at the time, but one too Latin-bound (*gratia plena*) for Luther's taste. In fact, he admitted a real

preference for the even more homely, idiomatic translation *du liebe Maria:* had the angel greeted her in German, that is what he would have said.

In determining the historical significance of Luther's Bible on the German language, one historian has recently emphasized that *what* was translated was more important than *by whom*. In the Christian West, the vernacular Bible – as no other text until very recently, read and listened to daily by members of the Christian faith – could not but have had influence on the languages in which it appeared, as for example the King James Version has had on English. Cautious recent scholars stress that much of Luther's German, however, was established by the time he used it in his translation, and other aspects of modern Standard German developed after the mid-16th century. It can be stated axiomatically that the press, becoming as it did so widely used by the forces of Protestantism and Catholicism in the sixteenth century and beyond, was the technology most responsible for the transformation of all early modern Christianity. A full exposition of printing's implications for the history of language is beyond the scope of this article. However, suffice it here to note the obvious: the printed vernacular Bible, to the extent that it fixed a popular text and allowed for its wide dissemination, provides the historian of language with a standard against which to judge the malleability and the resistance of language speakers to the standardization of their language.

In the case of the Luther Bible and the development of a standardized German, comparison between the 1522 and 1545 editions of the New Testament is particularly revealing. For example, it shows that orthography is an area of the written language on which Luther had no wide or lasting influence. This is also an area which printers themselves took to changing as they set the type and varied spelling and punctuation as they saw fit. Another kind of limit to the appropriation of Luther's German can be seen in the resistance to the unaccented terminal *e* in some German plurals and dative singulars, characteristic of the Saxon dialect and used in the Luther Bible. The so-called *Luther-e* was long resisted in the German-speaking Catholic South, where it had not been common before the Reformation and where it was resisted from the 16th-century onward for confessional reasons. Allied with the southern Germans, the Allemanic speakers in southwestern Germany and the Swiss Confederation resisted many aspects of Luther's German, but in these more Protestant regions, clearly without the confessional overtones. And today for reasons quite removed from the earlier ecclesiastical ones, the *Luther-e* is gradually disappearing from both spoken and written German everywhere.

In conclusion, Luther's influence on the development of early high German should not be underestimated. Luther had an unparalleled ear for the German language and was a vigorous author. But it should also be understood, in contradistinction to the enthusiasm for his linguistic paternity on the part of many 19th-century linguists, that most of the language characteristics of the Luther Bible had precedent before 1522. Furthermore, early high German was still to develop into the literary new high German of the 17th century and later. In this regard, Werner Besch, a distinguished historian of the German language, has suggested a simile with which to understand where Luther belongs in the pantheon of German writers: Besch uses the image of the medieval retable, in which the patron is painted modestly into the corner of a tableau filled with the artistic representation of some laudable religious event or theological truth: the subject of this painting is the vernacular Bible; the modest patron, Luther. Besch notes that that is an understanding of Luther's role in the development of the vernacular that Luther himself would surely accept.

Luxembourg: Language Situation

H Baetens Beardsmore, Université Libre de Bruxelles, Brussels, Belgium

© 2006 Elsevier Ltd. All rights reserved.

The Grand Duchy of Luxembourg, a country of 2586 km^2 and with a population in 2004 of 462 690 inhabitants, is a unique case in Europe, where the totality of the indigenous population is to some extent trilingual. The languages spoken are Luxembourgish (Luxembourgeois), German, and French. Approximately 30% of the population consists of immigrants, the majority of Portuguese or Italian background. Luxembourgish is the symbol of national identity and is the only cultural feature that clearly distinguishes the citizens from those of neighboring countries. Since 1938 naturalization has been made dependent on its knowledge.

Luxembourgish is a Germanic language related to Low German (Low Saxon). To some it is a dialect and has been classified as a partially standardized language, given its restricted literary tradition, or as a neglected minority mother tongue. It includes many loanwords from German and French, lacks vocabulary and styles to handle technological concepts, and given that it is primarily an oral mode of expression, has fairly elementary syntax with few subordinate clauses and restricted tense, mood, and case variations.

It was made a compulsory subject in elementary education in 1912, with an official spelling and textbook, and was declared the national language in 1983, but its use, though widespread, is limited. French and German, together with Luxembourgish, are official languages and all three are vehicles of instruction for the whole school population at different stages of the education system.

The system is intended to bring everyone in the country to some level of trilingual proficiency. In compulsory nursery education at ages four and five, Luxembourgish is used exclusively. This is partially intended to help anchor national identity and also to integrate immigrant children. In primary school, German gradually replaces Luxembourgish. German is taught as a subject in Grade 1 of primary school and is the first language of reading and writing. By the end of primary school the transition must be made to the exclusive use of German for all subjects except language lessons in Luxembourgish and French. The third language, French, is introduced as a subject in Grade 2 of primary education. The education system operates on the principle of introducing children to schooling in the majority language, Luxembourgish, followed by a related but distinct L2 (German) as a subject, but not a medium of instruction for nonlanguage subjects, in Grade 1, prior to a gradual elimination of the L1 in favor of the L2 as medium of instruction. The L3 (French) is introduced as a subject in primary education, in preparation for its use as a medium in secondary education. Mathematics is taught entirely through French in secondary schools and depending on the orientation, French may increase as a medium for nonlanguage subjects as schooling progresses, while the use of German decreases.

This complex system results in a working knowledge of three languages for the entire population. Proficiency depends on the type of education followed, those in general education having higher proficiency in French through more contact hours with the language than those in technical or vocational education.

Luxembourgish is the language most used (but not exclusively) by all social categories for oral exchanges in private life, but in written private communication the order of preference is German, French, Luxembourgish. In the work sphere the order of preference for oral communication is Luxembourgish, French, German, but for written communication the order is French, followed by German, with no Luxembourgish. With the administration citizens have the right to use any of the three languages and the administration is expected to reply in whichever of the three is preferred by the citizen "where possible." Since the legal system operates entirely in French it is not always possible to use another language.

Luxembourgish

G Newton, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Luxembourgish *(Lëtzebuergesch)*, genetically related to German, is traditionally grouped with the West Moselle Franconian dialects. However, early Salic Frankish influence and later close attachment to the Low Countries, France, and Spain have allowed it to develop an identity separate from that of the neighboring dialects in Germany. Earliest documents from the area date from the 9th century, with modern literary forms beginning in the 1820s. Various orthographies exist, including the strictly phonemic *Lezebuurjer Ortografi* (1946). Little used, this remained official until replaced in 1975 by the system of the *Luxemburger Wörterbuch*. Modifications to this were introduced in 1999.

In 1939, Luxembourg naturalization was made dependent on knowledge of the language. In 1984, *Lëtzebuergesch* was legally acknowledged as the national language of the Grand Duchy. Syntactically, *Lëtzebuergesch* is similar to German, although case loss has reduced the possibilities of object-verb-subject (OVS) ordering. Parataxis predominates, though hypotaxis is frequent (subject-object-verb (SOV) ordering). In morphology, nominative and accusative have fallen together, assuming accusative form. Third-person pronouns show northern /h/ (NHG = New High German): *hien*, *hatt, hinen* NHG *er*, *es*, *ihnen* 'he, it, them'. Noun plurals are most commonly in <e(n)>, though other patterns occur. There is, however, no plural in <s>. The pronouns *mir* NHG *wir* 'we' and *dir* NHG *ihr/Sie* 'you (plural and polite)' arise from false division of verbal endings. NHG *uns* 'us' appears as *äis/eis* (koine) and *ons* (Luxembourg city). Adjectival comparison is chiefly with *méi* NHG *mehr* 'more', though occasional synthetic forms occur. In compound nouns, a linking <s> is frequently present, e.g., *Plastikstut* NHG *Plastiktasche* 'plastic bag', *Autosdier* NHG *Autotür* 'car door'. Tenses comprise present (*ech gesinn* NHG *ich sehe*), perfect (*ech hu gesinn* NHG *ich habe gesehen*), and pluperfect (*ech hat gesinn* NHG *ich hatte gesehen*); the future can be periphrastic (*ech wäerd gesinn* NHG *ich werde sehen*), but is mainly a function of the present tense (*ech kommen iwwermar* NHG *ich komme übermorgen*). Some indicative (*ech gesouch* NHG *ich sah*) and subjunctive (*ech geséich* NHG *ich sähe*) preterites also occur, though these are more frequent in the north (Oesling); pluperfect subjunctives (*ech hätt gesinn* NHG *ich hätte gesehen*) occur frequently. The auxiliary verb *ginn* NHG *geben* = *werden* 'give = become' is used to form analytical conditionals (*ech géif gesinn* NHG *ich würde sehen*) and passives (*ech gouf gesinn* NHG *ich wurde gesehen* 'I was seen'). Present tense first-person singulars inflect <e(n)> (*ech sangen* NHG *ich singe*).

Consonants are in voiced/voiceless opposition, with final neutralization. The High German sound shift is incomplete (*dat* NHG *das/dass* 'that', *op* NHG *auf* 'on', *Pond* NHG *Pfund* 'pound', *Korf* NHG *Korb* 'basket', *Dall* NHG *Tal* 'valley') and intervocalic /g/ is often absent, e.g., *Won*, *Vull* NHG *Wagen*, *Vogel* 'wagon, bird'. Some velarization of dental nasals (*zéng*, *brong* NHG *zehn*, *braun* 'ten, brown') is also present, though this is stronger in the north of Luxembourg, which also has velarized plosives, e.g., *Lekt*, *néck* (koine *Leit*, *net*) NHG *Leute*, *nicht* 'people, not'. Medial and final /s/ combinations are liable to palatization (*Meeschter* NHG *Meister* 'master'), more strongly in the southwest (*Fënschter* NHG *Fenster* 'window'). Final /n/ is 'mobile' (*Eifler Regel*) and is retained only before a following vowel, /h/ or a dental (*den Dag*, but *de Mann* NHG *der/den Tag*, *der/den Mann*), or at juncture. Middle High German (MHG)

Luxembourgish *(Lëtzebuergesch)*, genetically related to German, is traditionally grouped with the West Moselle Franconian dialects. However, early Salic Frankish influence and later close attachment to the Low Countries, France, and Spain have allowed it to develop an identity separate from that of the neighboring dialects in Germany. Earliest documents from the area date from the 9th century, with modern literary forms beginning in the 1820s. Various orthographies exist, including the strictly phonemic *Lezebuurjer Ortografi* (1946). Little used, this remained official until replaced in 1975 by the system of the *Luxemburger Wörterbuch*. Modifications to this were introduced in 1999.

In 1939, Luxembourg naturalization was made dependent on knowledge of the language. In 1984, *Lëtzebuergesch* was legally acknowledged as the national language of the Grand Duchy. Syntactically, *Lëtzebuergesch* is similar to German, although case loss has reduced the possibilities of object-verb-subject (OVS) ordering. Parataxis predominates, though hypotaxis is frequent (subject-object-verb (SOV) ordering). In morphology, nominative and accusative have fallen together, assuming accusative form. Third-person pronouns show northern /h/ (NHG = New High German): *hien*, *hatt, hinen* NHG *er*, *es*, *ihnen* 'he, it, them'. Noun plurals are most commonly in <e(n)>, though other patterns occur. There is, however, no plural in <s>. The pronouns *mir* NHG *wir* 'we' and *dir* NHG *ihr/Sie* 'you (plural and polite)' arise from false division of verbal endings. NHG *uns* 'us' appears as *äis/eis* (koine) and *ons* (Luxembourg city). Adjectival comparison is chiefly with *méi* NHG *mehr* 'more', though occasional synthetic forms occur. In compound nouns, a linking <s> is frequently present, e.g., *Plastikstut* NHG *Plastiktasche* 'plastic bag', *Autosdier* NHG *Autotür* 'car door'. Tenses comprise present (*ech gesinn* NHG *ich sehe*), perfect (*ech hu gesinn* NHG *ich habe gesehen*), and pluperfect (*ech hat gesinn* NHG *ich hatte gesehen*); the future can be periphrastic (*ech wäerd gesinn* NHG *ich werde sehen*), but is mainly a function of the present tense (*ech kommen iwwermar* NHG *ich komme übermorgen*). Some indicative (*ech gesouch* NHG *ich sah*) and subjunctive (*ech geséich* NHG *ich sähe*) preterites also occur, though these are more frequent in the north (Oesling); pluperfect subjunctives (*ech hätt gesinn* NHG *ich hätte gesehen*) occur frequently. The auxiliary verb *ginn* NHG *geben* = *werden* 'give = become' is used to form analytical conditionals (*ech géif gesinn* NHG *ich würde sehen*) and passives (*ech gouf gesinn* NHG *ich wurde gesehen* 'I was seen'). Present tense first-person singulars inflect <e(n)> (*ech sangen* NHG *ich singe*).

Consonants are in voiced/voiceless opposition, with final neutralization. The High German sound shift is incomplete (*dat* NHG *das/dass* 'that', *op* NHG *auf* 'on', *Pond* NHG *Pfund* 'pound', *Korf* NHG *Korb* 'basket', *Dall* NHG *Tal* 'valley') and intervocalic /g/ is often absent, e.g., *Won*, *Vull* NHG *Wagen*, *Vogel* 'wagon, bird'. Some velarization of dental nasals (*zéng*, *brong* NHG *zehn*, *braun* 'ten, brown') is also present, though this is stronger in the north of Luxembourg, which also has velarized plosives, e.g., *Lekt*, *néck* (koine *Leit*, *net*) NHG *Leute*, *nicht* 'people, not'. Medial and final /s/ combinations are liable to palatization (*Meeschter* NHG *Meister* 'master'), more strongly in the southwest (*Fënschter* NHG *Fenster* 'window'). Final /n/ is 'mobile' (*Eifler Regel*) and is retained only before a following vowel, /h/ or a dental (*den Dag*, but *de Mann* NHG *der/den Tag*, *der/den Mann*), or at juncture. Middle High German (MHG)

<î, û, iu> (*îs* 'ice', *trîben* 'drive', *hûs* 'house', *liute* 'people', *hiulen* 'howl') appear as /ɛːi/ or /ɑi/ (*Äis* NHG *Eis*, *dreiwen* NHG *treiben*), /ɑːʊ/ (*Haus* NHG *Haus*), /ɑi/ or /ɑʊ/ (*Leit* NHG *Leute*, *haulen* NHG *heulen*), and <ie, uo, üe> (*brief* 'letter', *fuoz* 'foot', *vüeze* 'feet') appear as /ei/ (*Bréif* NHG *Brief*), /ou/ (*Fouss* NHG *Fuß*), /ei/ (*Féiss* NHG *Füße*). MHG <ei, ou> (*vleisch* 'flesh', *boum* 'tree') have the reflexes /eː/ (*Fleesch* NHG *Fleisch*), /aː/ (*Bam* NHG *Baum*). However, all of these examples may also be subject to allophonic variation, and shortened forms are common. A shift of West Germanic /i/ to /a/ is also a strong characteristic of the language: *Wand* NHG *Wind* 'wind'. Derounding (*Läffel*, *fënnef* NHG *Löffel*, *fünf* 'spoon, five') and lowering (*domm* NHG *dumm* 'stupid') are also found, as are elements of 'correption' (an abrupt rise and fall of vowel pitch; only vestigially present in Luxembourgish, e.g., *stäif/steif* NHG *steif* 'stiff') and 'circumflexion' (a rise and fall of vowel pitch, accompanied by up to three times normal length), e.g., *den Hals* (nom./acc.) NHG *der/den Hals* 'neck' (not circumflected); *dem Haals* (dat.) NHG *dem Hals(e)* (circumflected). Another element is the *Schwebelaut* (a lengthening of consonants), which occasionally marks a difference in meaning, e.g., *voll* (short /l/, MHG *vol*) NHG *voll* 'full', *voll* (long /lː/, MHG *volle)* NHG *voll* 'drunk'.

Samuel David Luzzato (often abbreviated as Shedal) was born in Trieste, Italy, on August 22, 1800, and died in Padua on September 30, 1865. He was educated in the best Talmudic traditions by Abraham Eliezer ha-Levi, the Chief Rabbi of Trieste. His father, himself an accomplished Talmudist, taught him Hebrew at home.

Luzzatto's precocious talents were noticed early in his childhood. At the age of 11 he undertook to write a Hebrew grammar in Italian, translated into Hebrew

the life of Æsop, and wrote exegetical notes on the Pentateuch. After the death of his mother in 1814, Luzzato had to do household work in addition to helping his father in his work. But this did not prevent him from pursuing his intellectual and creative interests. By 1815 he had amassed a collection of 37 poems that became the basis of his poetry collection *Kinnor Na'im* (1825). He completed a full treatise on the Hebrew vowels, *Ma'amar ha-Nikkud,* in 1817, and the following year he started to write his *Torah Nidreshet*, a philosophical-theologial exposition of the Torah in 24 essays, which was translated into Italian and published in 1879 by M. Coen-Porto. In 1829 he was appointed professor at the rabbinical college of Padua.

Among his most important works in Hebrew and Aramaic philology, besides those noted above, are *Prolegomena ad una grammatica ragionata della lingua ebraica* (Padua, 1896); *Grammatica della lingua ebraica* (Padua, 1853–1869); *Elementi grammaticali del caldeo biblico e del dialetto talmudico* (Padua, 1865; German transl. by Krüger, Breslau, 1873; English transl. by Goldammer, New York, 1876); *Ma'amar bi-Yesodei ha-Dikduk*, a treatise on Hebrew grammar (Vienna, 1865), and *Ketavim Ivriyyim*, from 1913, the unfinished edition of his Hebrew writings.

Luzzatto was the first Jewish scholar to give importance to Syriac and Samaritan in understanding the Aramaic translation (Targum) of the Hebrew Bible. His legacy includes a large number of exegetical works, both in Hebrew and in Italian. His son collected 89 of his letters, published as *Peninei Shadal* (The pearls of Samuel David Luzzatto). These letters include essays of bibliographical interest (numbers i.–xxii.); liturgical-bibliographical subjects (xxiii.–xxxi.); Biblical-exegetical letters (xxxii.–lii.), including a commentary on Ecclesiastes and a letter on Samaritan writing; other exegetical letters (liii.–lxii.); grammatical discussions (lxiii.–lxx.); historical notes (lxxi.–lxxvii.); philosophical letters (lxxviii.–lxxxii.), including letters on dreams and on Aristotelian philosophy; and theological discussions (lxxxiii.–lxxxix).

Lying, Honesty, and Promising

D Owens, University of Sheffield, Sheffield, UK

Promising and asserting are both speech acts, and as such they are regulated by practical norms as well as linguistic norms (e.g., norms of etiquette). Here we shall be concerned with the **moral** norms that govern these speech acts.

Informational Theories

Many philosophers take the view that the morality of an act – its rightness or wrongness – is a function of the harms and benefits this act brings to the agent and to others. These philosophers also hold that the main way promises and assertions affect the interests of human beings is when they serve as sources of information. So, they conclude, both promises and assertions are morally significant principally because, and in so far as, they purport to offer information. Let's call this the 'informational' view of the morality of promise and assertion. On this view, morality censures an unfulfilled promise or a false assertion because these deeds can harm others by giving them false information.

We are all obliged to take due care not to lead others to form false beliefs, at least where this might be harmful to them (Scanlon, 1998: 300). This obligation means that we must not set out to deceive people by making them insincere promises or telling them things that we know to be false. But it also means that we mustn't change our minds about what we promised we were going to do (without good reason) or make an assertion without adequate evidence. Someone who accepts a promise standardly forms the expectation that the promisor will perform, and they may rely on this expectation to their detriment. Someone who believes an assertion is similarly exposed, if this assertion turns out to be false. I'll deal

Lying, Honesty, and Promising

D Owens, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Promising and asserting are both speech acts, and as such they are regulated by practical norms as well as linguistic norms (e.g., norms of etiquette). Here we shall be concerned with the **moral** norms that govern these speech acts.

Informational Theories

Many philosophers take the view that the morality of an act – its rightness or wrongness – is a function of the harms and benefits this act brings to the agent and to others. These philosophers also hold that the main way promises and assertions affect the interests of human beings is when they serve as sources of information. So, they conclude, both promises and assertions are morally significant principally because, and in so far as, they purport to offer information. Let's call this the 'informational' view of the morality of promise and assertion. On this view, morality censures an unfulfilled promise or a false assertion because these deeds can harm others by giving them false information.

We are all obliged to take due care not to lead others to form false beliefs, at least where this might be harmful to them (Scanlon, 1998: 300). This obligation means that we must not set out to deceive people by making them insincere promises or telling them things that we know to be false. But it also means that we mustn't change our minds about what we promised we were going to do (without good reason) or make an assertion without adequate evidence. Someone who accepts a promise standardly forms the expectation that the promisor will perform, and they may rely on this expectation to their detriment. Someone who believes an assertion is similarly exposed, if this assertion turns out to be false. I'll deal

with informational theories of promising first and then move onto assertion.

Information theorists of promissory obligation fall into two categories. First, there are those (sometimes called 'expectation theorists') who argue that we are all under an obligation not to mislead others about how we shall behave in the future and that this obligation is why we ought not to make them promises that we do not fulfill (Scanlon, 1998: Chap. 7; Thomson, 1990: Chap. 12). Second, there are those who argue that we are obliged to fulfill our promises only where there is an up and running practice of fulfilling one's promises: prior to this, there is no promissory obligation. For such 'practice theorists,' promissory obligation is conventional (Hume, 1978: Book III, Part II, Section V; Anscombe, 1981; Prichard, 1968).

Practice theories differ from expectation theories in their account of how the obligation to keep a promise arises from our interest in having correct information about how other people are going to behave. According to the practice theorist, we can create expectations of performance in our audience by uttering words like "I promise" only where there is an actual practice of making such utterances true, i.e., where people have come to feel some obligation to make them true. So one can't explain the moral significance of this utterance simply by reference to the expectations it creates. Still the practice theorist agrees with the expectation theorist that we are obliged to maintain the practice of promise-making where it exists, because this practice serves our information interest and thereby aids the coordination of behavior.

Turning now to assertion, there is much controversy among philosophers of language about the extent to which language in general, and assertion in particular, involve social convention. For example, Davidson maintains that "there is no known, agreed upon, publicly recognizable convention for making assertions" (Davidson, 1984: 270), and he thinks the same is true of promising. On the other hand Fried urges that the promisor has "intentionally invoked a convention whose function it is to give grounds – moral grounds – for another to expect the promised performance" and "to abuse that confidence is like . . . lying: the abuse of a shared social institution that is intended to invoke the bonds of trust" (Fried, 1980: 16). Thus, there is a division among information theorists of the morality of assertion parallel to that between expectation and practice theorists of promissory obligation.

It has long been debated whether there is any morally significant difference between lying to someone and deceiving them in a more oblique fashion (e.g., by way of false implicatures, deliberate ambiguity, or by leaving misleading evidence around, etc.). And this debate reflects a genuine ambivalence in our everyday attitudes. Where we feel entitled to deceive others – for the sake of their health for instance – many of us are still inclined to go to the trouble of trying to avoid telling a direct lie. On the other hand, where such deception is wrong, the wrong is seldom thought to be mitigated just because a direct lie was avoided.

There is a tradition of thought, however, according to which lying is always wrong, but we are sometimes permitted to deceive in other ways (Aquinas, 1966: II-II 110 a3; MacIntyre, 1995: 309–318). But many contemporary writers have expressed doubts about whether the manner of the deception could by itself make a serious moral difference (Sidgwick, 1981: 354–355; (Williams, 2002: 100–110). An expectation theorist who maintains that the wrong of lying is only the wrong of deception will share these doubts (Scanlon, 1998: 320). On the other hand, a practice theorist of the morality of assertion may allow that, in addition to any harm he does to the person he deceives, the liar is abusing and thereby undermining a valuable social practice (Kant, 1991: 612), namely the use of language to convey information.

Noninformational Theories

Until now, we have been assuming that what makes an act, including a speech act, wrong is, some harm that it does to those it wrongs in the end. There are many moral theorists who reject this assumption, and it is open to them to propound noninformational theories of what is wrong with a lie or a broken promise. Rather than attempt a comprehensive classification of noninformational theories, I shall consider one such theory of promising and one such theory of lying, both taken from Kant.

Take promising. Kant locates the moral significance of promising not in the information interests it serves but rather in the fact that it grants the promisee a certain moral authority over the promisor: it entitles the promisee to require the promisor to perform and thus deprives the promisor of a certain moral freedom (Kant, 1996: 57–61). If I promise you a lift home, I am obliged to give you a lift unless you release me from this promise. This line of thought was central to classical theories of promissory obligation (Hobbes, 1991: Chap. 2) and has found an echo in some contemporary writing (Hart, 1967: 60). For these authors, a breach of promise wrongs the promisee, whether or not it also harms them by inducing false expectations in them, because it flouts the moral authority that the promisee has acquired over the promisor.

On this view, informational theories miss what is distinctive about promising. There are many ways of influencing people's expectations and of co-ordinating your behavior with others (Raz, 1977: 215–216). For example, one can predict that one will do something or even express a sincere intention to do something, while making it clear that one is not promising. To promise to do it is to express the intention to undertake an obligation to do it (Searle, 1969: 60), an obligation that mere expressions of intention or predictions do not bring down on the speaker, however firm or confident they may be. If I predict, on excellent evidence, that I shall be going in your direction because the police will be towing my car in that direction, I have not committed myself to making it true that I shall be going in your direction when that prediction threatens to be falsified.

Turning now to lying, Kant makes a firm distinction between wrong one does in deceiving someone and the wrong one does by lying (Kant, 1996: 182–184). One can lie without deceiving (e.g., when one knows one won't be believed) and one can deceive without lying. On deceiving someone you may wrong them but, according to Kant, when you lie, the person you wrong is yourself. The liar violates a duty to himself (though this violation need not involve harming himself). On explaining the nature of this wrong, Kant follows thinkers like Aquinas in attributing a natural teleology to speech:

> communication of one's thoughts to someone through words that yet (intentionally) contain the contrary of what the speaker thinks on the subject is an end that is directly opposed to the natural purposiveness of the speaker's capacity to communicate his thoughts (Kant, 1996: 182).

In lying, one violates a duty to oneself by abusing one's own faculties, by using oneself "as a mere means (a speaking machine)" (Kant, 1996: 183). It may be possible to capture Kant's basic idea here without reference to natural teleology or duties to self if we adopt a certain view of assertion.

One can distinguish two currently influential theories of assertion. In the first, inspired by Grice, asserting that p is a matter of uttering something with the intention of thereby getting your audience to believe that p, by means of their recognition of that very intention (Grice, 1989). If something like this statement is correct, the moral significance of an utterance *qua* assertion must lie solely in the effect it is trying to achieve, i.e., in the effect that the assertion has on the beliefs of others. In the second view of assertion, asserting that p is more like promising that p. In promising, someone intentionally undertakes an obligation to perform: undertaking such obligations is what promising consists in. Similarly to assert a certain proposition is, on this view, to intentionally undertake an obligation to ensure that one asserts only what is true (Dummett, 1973: 299–302) and, perhaps, to defend one's assertions as true, should they be challenged (Brandom, 1983). Putting oneself under such obligations is what assertion consists of.

Once the second view is in play, we can say what is wrong about lying without making reference to the effect that the lie has on others. A liar is in the wrong not because he is wronging someone but because he knows that he is taking on obligations he cannot discharge. In this way, lying differs from deception that wrongs the deceived when it harms their interests in some way. Deception is an offence against others while lying is an offence against truth. Provided morality is not solely concerned with harm, this offence may be counted as a moral wrong.

Lyons, John, Sir (b. 1932)

G Brown, University of Cambridge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

John Lyons' first degree was in classics at Cambridge (1953), where he returned in 1956 to research on the semantics of Plato's vocabulary for knowledge and understanding, supervised by W. S. Allen. Allen introduced him to Chomsky's *Syntactic structures,* which provided a technical framework in which he could formulate the structural relationships among his selected words. In 1957, he moved to a lectureship at the School of Oriental and African Studies (SOAS), where his local Ph.D. supervisor was R. H. Robins. His views on linguistics and on the philosophy of language were also strongly influenced by C. E. Bazell, then Head of Department. His thesis, published in 1963, "was probably the first work in semantics ... to be based overtly on the principles of generative grammar" (Lyons, 1995a:233).

Lyons spent a year (1960–1961) working on a machine-translation project directed by F. W. Householder at Indiana, where he could supplement his knowledge of the history of linguistics, culminating in European studies in the 19th and early 20th centuries. There he experienced the very different U.S. tradition of linguistic study in a major center for linguistics and anthropology.

After his year in the United States, Lyons lectured at Cambridge until 1964, when he was appointed to the Chair of General Linguistics in Edinburgh. Lyons, a 32-year-old professor, with a cropped American haircut, remarkable intellectual and physical energy, and a dazzling French wife, caused comment in the ancient Scottish university. An inspiring teacher, he remodeled his department and its postgraduate program, attracting a galaxy of student talent, as he did subsequently in Sussex; a remarkable number of his students went on to chairs in linguistics. Meanwhile, he wrote the two substantial books that cemented his reputation: *Introduction to theoretical linguistics* (1968) and *Semantics* (1977), and, as founding editor of the *Journal of Linguistics,* established it as a leading international journal by judicious choice of initial contributors.

In 1976, Lyons moved to a new Chair of Linguistics at the University of Sussex, where he produced a stream of publications, notably *Language, meaning and context* (1981). During this period he was involved in the British Academy, the Social Sciences Research Council, and the European Science Foundation. In 1981, appointed Pro-Vice-Chancellor at a moment when university funding was savagely reduced, he was immediately involved in planning the elimination or reduction in size of several departments, a bruising and distressing experience.

In 1984, he was elected Master of Trinity Hall, Cambridge. Within months of his return to Cambridge, cancer was diagnosed and a series of courses of chemotherapy and radiotherapy began, lasting for years. Despite the debilitating effects of the intermittently progressing disease and its treatment, the requirements of college administration, and new demands for fund raising brought about by funding reductions, Lyons brought out several papers and three books: a 3rd edition of *Chomsky* (1991a, with major revisions and a new chapter); *Natural language and universal grammar* (1991b, collected earlier papers, with copious updated notes); and *Linguistic semantics* (1995b, a more detailed and technical version of Lyons, 1981). His personal history was published in 2002. He retired in autumn of 2000.

Lyons' approach to semantics is stated clearly: "I take a very broad view of semantics: for me ... linguistic semantics is the study of all the different kinds of meaning that are systematically encoded in natural languages.... I include within linguistic semantics a good deal of what many ... would classify as pragmatics" (1981:9). In part, his eclecticism may be attributed to a rare breadth and depth of knowledge of classical linguistics, combined with 19th and 20th century European, as well as U.S., linguistic traditions, but he did not confine his reading, thinking, or research to 'linguistics' narrowly conceived. He contributed to psycholinguistic research (cf. Lyons and Wales, 1966; Lyons, 1981, 1996) and to stylistics (1980). His work is informed by anthropology, as well as by the philosophy of language and of mind. Repeatedly, he urged formal semantics to expand its interests beyond a narrow 'intellectualist' concern

His views on linguistics and on the philosophy of language were also strongly influenced by C. E. Bazell, then Head of Department. His thesis, published in 1963, "was probably the first work in semantics ... to be based overtly on the principles of generative grammar" (Lyons, 1995a:233).

Lyons spent a year (1960–1961) working on a machine-translation project directed by F. W. Householder at Indiana, where he could supplement his knowledge of the history of linguistics, culminating in European studies in the 19th and early 20th centuries. There he experienced the very different U.S. tradition of linguistic study in a major center for linguistics and anthropology.

After his year in the United States, Lyons lectured at Cambridge until 1964, when he was appointed to the Chair of General Linguistics in Edinburgh. Lyons, a 32-year-old professor, with a cropped American haircut, remarkable intellectual and physical energy, and a dazzling French wife, caused comment in the ancient Scottish university. An inspiring teacher, he remodeled his department and its postgraduate program, attracting a galaxy of student talent, as he did subsequently in Sussex; a remarkable number of his students went on to chairs in linguistics. Meanwhile, he wrote the two substantial books that cemented his reputation: *Introduction to theoretical linguistics* (1968) and *Semantics* (1977), and, as founding editor of the *Journal of Linguistics,* established it as a leading international journal by judicious choice of initial contributors.

In 1976, Lyons moved to a new Chair of Linguistics at the University of Sussex, where he produced a stream of publications, notably *Language, meaning and context* (1981). During this period he was involved in the British Academy, the Social Sciences Research Council, and the European Science Foundation. In 1981, appointed Pro-Vice-Chancellor at a moment when university funding was savagely reduced, he was immediately involved in planning the elimination or reduction in size of several departments, a bruising and distressing experience.

In 1984, he was elected Master of Trinity Hall, Cambridge. Within months of his return to Cambridge, cancer was diagnosed and a series of courses of chemotherapy and radiotherapy began, lasting for years. Despite the debilitating effects of the intermittently progressing disease and its treatment, the requirements of college administration, and new demands for fund raising brought about by funding reductions, Lyons brought out several papers and three books: a 3rd edition of *Chomsky* (1991a, with major revisions and a new chapter); *Natural language and universal grammar* (1991b, collected earlier papers, with copious updated notes); and *Linguistic semantics* (1995b, a more detailed and technical version of Lyons, 1981). His personal history was published in 2002. He retired in autumn of 2000.

Lyons' approach to semantics is stated clearly: "I take a very broad view of semantics: for me ... linguistic semantics is the study of all the different kinds of meaning that are systematically encoded in natural languages.... I include within linguistic semantics a good deal of what many ... would classify as pragmatics" (1981:9). In part, his eclecticism may be attributed to a rare breadth and depth of knowledge of classical linguistics, combined with 19th and 20th century European, as well as U.S., linguistic traditions, but he did not confine his reading, thinking, or research to 'linguistics' narrowly conceived. He contributed to psycholinguistic research (cf. Lyons and Wales, 1966; Lyons, 1981, 1996) and to stylistics (1980). His work is informed by anthropology, as well as by the philosophy of language and of mind. Repeatedly, he urged formal semantics to expand its interests beyond a narrow 'intellectualist' concern

with the truth of propositions, to include the expression of subjectivity in the use of deixis, aspect, tense, and modality (and to consider not only alethic but also epistemic and deontic modality) (Lyons, 1977, 1981, 1995a,b). Benveniste's (1966) concern with the expression of subjectivity in language is consistently echoed by Lyons (1977, 1981, 1982, 1987, 1995a,b). Hence, he is conscious that features such as intonation and voice quality may systematically affect utterance meaning, expressing the speaker's subjective stance toward the content of the proposition (Lyons, 1977, 1987, 1995b). Detailed attention to deixis, particularly as the way the young child arrives at the notion of reference, permeates his work (1975, 1977, 1978, 1981, 1982, 1983, 1991, 1995b).

By virtue of his publications, his influential teaching, and his support for linguistics both nationally and internationally, Lyons held for 40 years a unique position in British linguistics. His contribution was formally recognized in 1987 when he was knighted 'for services to linguistics.'

M

Ma, Jianzhong (1844–1900)

Y Gu, The Chinese Academy of Social Sciences, Beijing, China

© 2006 Elsevier Ltd. All rights reserved.

Jianzhong Ma (马建忠), born on February 9, 1845 in the present-day Jiangsu Province, was a grammarian as well as a diplomat. He attended a missionary school in Shanghai and became a polyglot in Latin, Greek, English, and French. In August 1876 he went to study in Paris, France, majoring in diplomacy and law. In March 1880 he returned to China after completing his doctorate. He worked for the State Council and was subsequently assigned several important diplomatic missions abroad. In 1885, he worked in Shanghai, attending to post-Sino-French war business. Due to policy differences with his superiors, he resigned from the civil service post and dedicated himself to academic research. He died of a fever in 1900 in Shanghai. His best known work is *Mr Ma's grammar.*

In his lifetime, Ma was a very active reformist. His ever-lasting fame, however, lies in his academic work known as *Mashi Wentong* (马氏文通) in Chinese, which can be translated as 'Mr Ma's grammar.' It is generally recognized in linguistic circles that his grammar was the first systematic treatment of Chinese grammar. Some even argue that it was the first grammar of Chinese ever written. *Mashi Wentong*, originally entitled *Wentong*, was first published in 1898 by Shanghai Commercial Press. It was an immediate success. In 1954, Zhang Xichen edited an annotated version and renamed the work *Mr Ma's grammar with commentaries;* it was published by China Publishing House. The punctuated version published by Commercial Press in 1983 bore the well-known title *Mr Ma's grammar.* The latest version was edited by Lü Shuxiang and Wang Haifen, who called their edited work *Mr Ma's grammar with a reading guide*, and was published by Shanghai Education Press in 1986.

It is now generally held that, although the Chinese grammatical phenomena had been consciously analyzed in pre-*Mr Ma's grammar eras*, the examination was sporadic and fragmented. It was *Mr Ma's grammar* that gave the first, comprehensive treatment of Chinese grammatical phenomena. The author was versed both in archaic Chinese and in classic Chinese philology. His grammar, however, was as a whole not an integration of all the previous studies with which he was familiar. Rather, he was more influenced by Western grammars than by similar works in Chinese. Some commentators argue that *Mr Ma's grammar* drew substantial insights from French grammars, such as *General and rational grammar: The Port-Royal grammar*, by Antoine Arnauld and Claude Lancelot, edited and translated by Jacques Rieux and Bernard E. Rollin, published in 1975 by Mouton. So in essence, *Mr Ma's grammar* should be regarded as a successful attempt at applying Western grammatical theories to Chinese linguistic context. The language data Ma used for illustrations were from archaic written Chinese texts. The body of work consists of 10 chapters, the bulk of which analyzes parts of speech. Words are first divided into two major classes: *shi zi* (i.e., lexical words) and *xu zi* (i.e., functional words). *Shi zi* and *xu zi* are further classified into five and four subclasses, respectively; the former are (1) noun, (2) pronoun, (3) verb, (4) static, and (5) adjective and the latter are (1) preposition, (2) connective, (3) particle, and (4) interjective.

More than 100 years have passed since *Mr Ma's grammar* first appeared, a time long enough to assess its contribution. The traditional Chinese philology (called *xiao xue*, 小学) was threefold: *wen zi* (i.e., orthography), *yin yun* (i.e., phonology), and *xun gu* (i.e., lexical semantics). There was no place for grammar. *Mr Ma's grammar* enriches the traditional philology with a fourth component. To many Chinese grammarians, it was quite revolutionary, and it even updated the traditional discipline to the level of modern linguistics. Some of its critics, on the other hand, accused its author of over-Westernizing Chinese grammar. The Western notions of parts of speech and the syntactic categories such as subject, predicate, object, etc., should be scrutinized to see if they were appropriate for Chinese. To Ma, "Every country has its own grammar, and all grammars are more or less

similar. They differ from one another in sounds and writing scripts" (1983: Introduction).

Macedonia: Language Situation

V A Friedman, University of Chicago, Chicago, IL, USA

Introduction

The Republic of Macedonia (*Republika Makedonija*) is bordered by Bulgaria on the east, Greece on the south, Albania on the west, and Kosovo (administered under UNSCR 1244 as of this writing, 30 October 2004) and Serbia on the north. Although efforts to create a Macedonian literary language and an independent Macedonian state date from the 19th century, it was only on August 2, 1944 that Macedonian was declared the official language of the People's Republic of Macedonia (later the Socialist Republic of Macedonia) as one of the constitutive republics of the former Yugoslavia. The Macedonian parliament adopted its own constitution, thereby declaring independence, on November 17, 1991.

Language and the Law

The original preamble of the constitution defined Macedonia as the national state of the Macedonian people (*makedonskiot narod*) with full civil equality for the Albanians, Turks, Vlahs, Roms, and other nationalities (*nacionalnosti*). On November 16, 2001, the preamble was replaced with Amendment IV, which states that the citizens of the Republic of Macedonia, the Macedonian people, as well as citizens living within its borders who are part of the Albanian, Turkish, Vlah, Serbian, Romani, Bosniac, and other peoples, constitute the Republic of Macedonia. Articles 7, 48, and 54, and Amendments V and VIII guarantee minority language rights in administration, education, culture, and the judiciary. A key difference between the articles and the amendments is that while the articles guaranteed official use of minority languages in districts with a "majority or significant number" of minority language speakers, the amendments specify a significant number as 20%.

Language and Identity

In the two post-independence Macedonian censuses (1994 and 2002), six languages were in official use: Macedonian, Albanian, Turkish, Romani, Serbian (Serbo-Croatian), and Aromanian. The translation of census documents into Romani and Aromanian in 1994 represented the first such official use of these languages anywhere. **Table 1**, compiled from figures published by the Bureau of Statistics of the Republic of Macedonia (*Zavod za Statistika Republika Makedonija*), gives the figures for declared ethnicity in 1994 and 2002 and declared mother tongue in 1994. Almost all non-Macedonians speak Macedonian as a second language.

The category *Muslim*, dating from the Yugoslav period, was used by some Slavic-speaking Muslims who considered Macedonian, Serbian, and Croatian nationalities to be Christian. With the break-up of Yugoslavia, Bosniac activists claimed all Slavic-speaking Muslims as Bosniac. The figure in the 2002 census signals an acceptance of this identity by some Macedonian-speaking Muslims. Some Macedonian speakers declared Turkish or Serbian nationality on the basis of religious feeling (Muslim and Serbian Orthodox, respectively). The distinction between Muslim as an ethnic identity and as a religious identity is illustrated by the fact that in the 1994 census, a small number declared Muslim nationality and Catholic religion. Egyptians (in Macedonian, *Egipkani* or *Gupci*) are almost all Albanian-speaking Muslims (1856) or Macedonian-speaking Christians (961) whose ethnonym is cognate with the English *Gypsy*. These are descendants of long-settled, formerly Romani-speaking populations, but members of this group claim Egyptian descent. Judezmo (Judeo-Spanish) was spoken in Macedonia until March 11,

similar. They differ from one another in sounds and writing scripts" (1983: Introduction).

1943, when 7200 Jews were deported by the Nazis and their collaborators to the Treblinka death camp. Only 2% survived, and most of the survivors went to Israel, but a very small Jewish community was reestablished on December 26, 1944 and lives in Macedonia today.

Language in Education and the Media

Prior to 1991, as today, Albanian and Turkish had primary and secondary education, post-secondary teacher training, and academic departments at the University of Skopje. During the 1980s, support for Albanian- and Turkish-language education was curtailed, and the Albanian teachers' college was closed in 1986. In 1995, Albanian educational activists organized a controversial Albanian-language university in Tetovo. In 2001, with support from the international community, Southeast European University (SEEU) was opened in Tetovo with teaching in Albanian, Macedonian, and English. The percentage of Macedonian-speaking students rose from 1% when school began in 2001 to 26% in the fall of 2003. There are a few elementary school classes offering Romani and Aromanian.

The government-supported Albanian and Macedonian newspapers are both daily, the Turkish one is triweekly. There are private publications of various size and distribution in all of the minority languages. In 1989, only Turkish and Albanian were represented on Macedonian public television: each had 130 minutes a week. In 1991, TV programming in Romani and Aromanian was begun at 30 minutes a week. By 2000, the figures for minority-language programming on national public television (MTV 2) were 400 minutes a week for Albanian, 370 minutes a week for Turkish, and 60 minutes a week each for Romani, Aromanian, and Serbian (*Antena* No. 133, supplement to *Dnevnik*, October 27, 2000). Of 57 private local TV licenses given out in 1998 (after the passing of the Communications Act of 1997), 21 were for stations using minority languages, and of 80 private radio licenses, 26 had all or most programming in minority languages.

Macedonian in Neighboring Countries

Macedonian-speaking minorities living in neighboring countries have almost no linguistic rights. The one exception is a group of Christian Macedonian-speaking villages near Lake Prespa in southeastern Albania, which have primary education in Macedonian through grade 4. Radio programming in Macedonian is also permitted in Albania, as are cultural organizations. Macedonian activists in Greece and Bulgaria have organized cultural associations and published leaflets and newspapers, but they have been subject to government harassment.

Introduction

Modern Macedonian (*makedonski* in Macedonian) is a South Slavic language (Slavic, Indo-European). It is not to be confused with Ancient Macedonian, an Indo-European language of uncertain (but not Slavic) affiliation, whose most famous speaker was Alexander the Great. Macedonian is closest to Bulgarian and Serbian.

Macedonian is descended from the dialects of Slavic speakers who settled in the Balkan peninsula during the 6th and 7th centuries C.E. The oldest attested Slavic language, Old Church Slavonic, was based on dialects spoken around Salonica, in what is today Greek Macedonia. As it came to be defined in the 19th century, geographic Macedonia is the region bounded by Mount Olympus, the Pindus range, Mounts Shar and Osogovo, the western Rhodopes, the lower course of the river Mesta (Greek Nestos), and the Aegean Sea. Many languages are spoken in this region, but it is the Slavic dialects to which the glossonym *Macedonian* is applied. The region was part of the Ottoman Empire from the late 15th century until 1912 and was partitioned among Greece, Serbia, and Bulgaria (with a western strip of villages going to Albania) by the Treaty of Bucharest in 1913. The modern Republic of Macedonia, in which Macedonian is the official language, corresponds roughly to the southern part of the territory ceded to Serbia plus the Strumica valley. The population is 2 022 547 (2002 census). Outside the Republic, Macedonian is spoken by ethnic minorities in Albania, Bulgaria, Greece, and Kosovo as well as by émigré communities elsewhere. Greece does not recognize the existence of its ethnic minorities, Bulgaria insists that all Macedonians are really Bulgarians, Albania refused to include questions about language and ethnicity in its last census (2001), and there has not been an uncontested statistical exercise in Kosovo since 1981, so official figures on Macedonian speakers outside the republic are unavailable; estimates range to 700 000.

History

Modern Macedonian literary activity began in the early 19th century among intellectuals attempting to write their Slavic vernacular instead of Church Slavonic. Two centers of Balkan Slavic literacy arose, one in what is now northeastern Bulgaria, the other in what is now southwestern Macedonia. In the early 19th century, all these intellectuals called their language *Bulgarian*, but a struggle emerged between those who favored northeast Bulgarian dialects and those who favored western Macedonian dialects as the basis for what would become the standard language. Northeast Bulgarian became the basis of standard Bulgarian, and Macedonian intellectuals began to work for a separate Macedonian literary language. The earliest known published statement of a separate Macedonian linguistic identity was by

Introduction

Modern Macedonian (*makedonski* in Macedonian) is a South Slavic language (Slavic, Indo-European). It is not to be confused with Ancient Macedonian, an Indo-European language of uncertain (but not Slavic) affiliation, whose most famous speaker was Alexander the Great. Macedonian is closest to Bulgarian and Serbian.

Macedonian is descended from the dialects of Slavic speakers who settled in the Balkan peninsula during the 6th and 7th centuries C.E. The oldest attested Slavic language, Old Church Slavonic, was based on dialects spoken around Salonica, in what is today Greek Macedonia. As it came to be defined in the 19th century, geographic Macedonia is the region bounded by Mount Olympus, the Pindus range, Mounts Shar and Osogovo, the western Rhodopes, the lower course of the river Mesta (Greek Nestos), and the Aegean Sea. Many languages are spoken in this region, but it is the Slavic dialects to which the glossonym *Macedonian* is applied. The region was part of the Ottoman Empire from the late 15th century until 1912 and was partitioned among Greece, Serbia, and Bulgaria (with a western strip of villages going to Albania) by the Treaty of Bucharest in 1913. The modern Republic of Macedonia, in which Macedonian is the official language, corresponds roughly to the southern part of the territory ceded to Serbia plus the Strumica valley. The population is 2 022 547 (2002 census). Outside the Republic, Macedonian is spoken by ethnic minorities in Albania, Bulgaria, Greece, and Kosovo as well as by émigré communities elsewhere. Greece does not recognize the existence of its ethnic minorities, Bulgaria insists that all Macedonians are really Bulgarians, Albania refused to include questions about language and ethnicity in its last census (2001), and there has not been an uncontested statistical exercise in Kosovo since 1981, so official figures on Macedonian speakers outside the republic are unavailable; estimates range to 700 000.

History

Modern Macedonian literary activity began in the early 19th century among intellectuals attempting to write their Slavic vernacular instead of Church Slavonic. Two centers of Balkan Slavic literacy arose, one in what is now northeastern Bulgaria, the other in what is now southwestern Macedonia. In the early 19th century, all these intellectuals called their language *Bulgarian*, but a struggle emerged between those who favored northeast Bulgarian dialects and those who favored western Macedonian dialects as the basis for what would become the standard language. Northeast Bulgarian became the basis of standard Bulgarian, and Macedonian intellectuals began to work for a separate Macedonian literary language. The earliest known published statement of a separate Macedonian linguistic identity was by

Gjorgji Pulevski 1875, but evidence of the beginnings of separatism can be dated to a letter from the teacher Nikola Filipov of Bansko to the Bulgarian philologist Najden Gerov in 1848 expressing dissatisfaction with the use of eastern Bulgarian in literature and textbooks (Friedman, 2000: 183) and attacks in the Bulgarian-language press of the 1850's on works using Macedonian dialects (Friedman, 2000: 180).

The first coherent plan for a Macedonian standard language was published by Krste Misirkov in 1903. After World War I, Macedonian was treated as a dialect of Serbian in Serbia and of Bulgarian in Bulgaria and was ruthlessly suppressed in Greece. Writers began publishing Macedonian works in Serbian and Bulgarian periodicals, where such pieces were treated as dialect literature, but some linguists outside the Balkans treated Macedonian as a separate language. On August 2, 1944, Macedonian became the official language of what was then the People's Republic of Macedonia. Bulgaria recognized both the Macedonian language and its own Macedonian minority from 1946 to 1948. From 1948 to the 1960s, some Bulgarian linguists continued to recognize Macedonian as a separate Slavic language. When Macedonia declared independence from Yugoslavia in 1991, Bulgaria immediately recognized the state, but not the nationality or the language. In February 1999, the Bulgarian government officially recognized the Macedonian standard language.

Dialects

Macedonian dialects are divided by a major bundle of isoglosses running from northwest to southeast along the River Vardar, swerving southwest at the confluence of the Vardar and the Crna and continuing down the Crna and into Greece southeast of Florina (Lerin in Macedonian), then bifurcating north of Kastoria (Kostur in Macedonian) so that the remaining Macedonian-speaking villages in Greece and Albania form a transitional zone. The western region is characterized by a relatively homogeneous central area and five groups of peripheral dialects centered on towns around the western periphery. The eastern zone has six dialect groups with no regional center. Standard Macedonian is based on the west-central dialects, with elements from other dialects.

Orthography and Phonology

Macedonian is written in the Cyrillic alphabet, following the principle of one letter per sound, as in Serbian Cyrillic. Macedonian has three distinctive letters – ќ, ѓ, s – representing the voiceless and voiced dorsopalatal stops and the voiced dental affricate, respectively. Macedonian Cyrillic љ is, according to the standard (Koneski, 1967: 115), used to represent clear /l/ before consonants, before back vowels, and word-finally, where it can contrast with velar /ł/, e.g., бела [beła] 'white' F versus беља [bela] 'trouble'. The contrast is neutralized before front vowels, where only clear /l/ is prescribed. Some educated speakers pronounce љ as palatal [λ], influenced by the Serbian pronunciation of this letter and the fact that the same reflex occurs in the Skopje town dialect. Standard Macedonian has a five-vowel system (a, e, i, o, u), and most dialects outside the west-central area also have schwa, but of different origins in various regions. There is no letter to represent schwa in Macedonian Cyrillic; when it is necessary to do so, an apostrophe is prescribed. The western Macedonian dialects and the standard are characterized by fixed antepenultimate stress, e.g., *vodéničar* 'miller', *vodeníčari* 'millers', *vodeničárite* 'the millers'.

Morphology, Syntax, and Lexicon

Macedonian has masculine, feminine, and neuter genders. Aside from plurals and pronouns, the only remnants of Slavic substantival inflection in Macedonian are the masculine and feminine vocative, which are becoming obsolete; oblique forms for masculine proper names and a few kinship terms and other masculine animates, all facultative; and a quantitative plural for inanimate nouns, which is used only sporadically, except in a few common expressions. Macedonian has a three-way opposition in the postposed definite article – *-t-*'neutral', *-v-*'proximal', *-n-*'distal' – although these meanings can be based on speaker attitude as well as physical distance. The example in (1) is illustrative.

(1) raki-vče-to ќe mu go
brandy-DIM-DEF.NEUT FUT him.DAT it-ACC
dade-š na prijatel-ov od
give-2.sing.PRES to friend-DEF.MASC.PX from
naš-a-na vo frizer-ov
our-FEM.FEM.DEF.DS in freezer-DEF.MASC.PX
'Give the little [glass of] brandy to our friend here, from that [brandy] of ours, in the freezer here.'

The article attaches to the end of the first nominal in the noun phrase, i.e., not adverbs:

(2) ne mnogu po-star-i-te deca
not much COMP-old-PL-DEF.PL children
'the children that are not much older'

edna od mnogu-te naš-i zadač-i
one from many-DEF.PL our-PL problems-PL
'one of our many problems'

The Macedonian verb has both aorist/imperfect and perfective/imperfective aspectual oppositions, but imperfective aorists are now obsolete. Perfective presents and imperfects occur only after one of eight modal particles, although perfective presents can also be used in negative questions. Macedonian also developed a new perfect series using the auxiliary *ima* 'have' and an invariant neuter verbal adjective. The synthetic pasts are marked for speaker confirmation, while the descendent of the Common Slavic perfect, using the old resultative participle in *-l* (no longer a true participle, since it cannot be used attributively), is not marked for speaker confirmation and is therefore used when the speaker cannot or will not vouch for the truth of the statement, e.g., because it was reported: *Toj beše vo Moskva* 'He was in Moscow' (I saw him or accept the fact as established). *Toj bil vo Moskva* 'He was in Moscow' (I heard it but was not there myself, do not vouch for it, or do not believe it [nuance depending on context]). The verbal *l*-form is also used in the inherited Slavic pluperfect (with the auxiliary 'be' in the imperfect) and the inherited conditional (after invariant modal particle *bi*). The new pluperfect is formed with the imperfect of 'have' and the neuter verbal adjective. The new conditional uses the invariant future marker *ќe* plus the imperfect (perfective or imperfective) of the main verb. The *bi*-conditional tends to be used for hypothetical apodoses and the *ќe* conditional for irrealis.

The following are distinctively Macedonian lexical items: *saka* 'want, like, love', *bara* 'seek', *zboruva* 'speak', *zbor* 'word', *deka* 'that (relativizer)', *vaka* 'in this manner', *olku* 'this many'.

Introduction

This article surveys the state of the art in corpus-aided translation research, teaching, and practice. The 1990s saw a surge of interest in these areas as corpora became more easily accessible, corpus linguistics established itself as a central approach to the study of language, and translation/interpreting gained prominence as core subjects in academic curricula and learned discussions.

The focus of this article is specifically on translation, and it distinguishes between descriptive (including theoretical) aspects (Descriptive Translation Studies, or DTS for short) and applied (didactic and professional) aspects (Applied Translation Studies, or ATS for short). In so doing, we follow, albeit very superficially, Holmes's (1988) general taxonomy of translation studies.

Corpus-Based DTS

Precursors and Initiators

In the 1990s, the corpus approach came to be recognized as one of the major research paradigms in descriptive translation studies. Mona Baker (1993) argued that the discipline was at a turning point: the availability of electronic corpora made it possible to think of research directions beyond the simple comparison of an original and its translation, with its by then discredited reliance, implicit or explicit, on the notion of 'equivalence' (*see* **Approaches to Translation, Linguistic**; **Translational Equivalence**). This brought linguistic approaches to translation studies more in line with the so-called cultural turn in translation studies (*see* **Cultural, Colonialism and Gender Oriented Approaches to Translation**) (Lefevere and Bassnett, 1990).

While Baker's paper has generally been regarded as the main inspirer of the corpus-based approach, several precursors and co-founders should also be mentioned; first and foremost, Gideon Toury. Toury's (1980, 1995) target-oriented approach to translation research – which viewed translation as an act that concerns primarily the culture in which a text is translated – had important implications that were taken on by the corpus approach, namely, the downplaying of the source text as the authority against which to evaluate a translation, and the concurrent enlargment of the scope of research to include aspects of the sociocultural environment in which a text is (to be) translated. Much current research in this area seeks textual evidence of the existence of "translation norms" in Toury's sense, i.e., of those sociocultural constraints regulating the behavior of professional translators, which affect the 'acceptability' of any given translation at any given point in time.

Similarly, the search for translation universals is grounded in Toury's notion of "laws of translational behavior." One such law, the "law of growing standardization," for instance, tentatively states that "in translation, textual relations obtaining in the original are often modified [...] in favour of [more] habitual options offered by a target repertoire" (Toury, 1995: 268). Kenny (2001) investigated this hypothesis, using a corpus of original German literary texts translated into English, and reference corpora of the languages in question. She found that 'unusual,' creative collocations indeed tended to be 'normalized' in translation, i.e., in as many as 44% of cases in her corpus, more 'normal' words and expressions were chosen to translate unusual, creative ones.

On the empirical side, precursors to this body of research were Vanderauwera (1985) and Gellerstam (1986). Vanderauwera studied Dutch fiction translated into English between the late 1950s and 1980. In her corpus of around 70 novels (analyzed manually and on paper), she found evidence of normalization at different levels: translators tended to increase the fluency and coherence of their texts, making them more modern and more readable for their target audience and concealing their foreign origin.

Gellerstam (1986) used an innovative methodology involving original novels in Swedish and novels translated from English into Swedish. Corpora of this type, often referred to as 'monolingual comparable corpora,' have been very influential, as we see in the section 'Monolingual Comparable Corpora' (MCC). Gellerstam's aim was to find empirical evidence of *translationese*, i.e., that the Swedish used in translation from English was a special variety of the language heavily influenced by the English of the originals. An area in which translations are clearly influenced by the conventions of their source texts (or the genres the latter belong to) is reporting clauses, where, he found, sequences like *direct speech – subject – verb of saying – adverbial* were much more common in translated than in original Swedish fiction (cf., e.g., the English "'I'll hold it for you,' he said with insulting kindness").

The corpus-based approach to translation studies was thus largely characterized, particularly in its early days, by a target-oriented approach whereby the target text, language, and culture had priority over the corresponding source dimensions. At approximately the same time as Baker (1993), though in a separate line of research, Stig Johansson and colleagues (1994) at the University of Oslo were also creating resources and paradigms that would boost corpus research in translation considerably, with an eye toward the source as well as the target dimensions. In 1994, a research project was launched to build a bidirectional parallel corpus, i.e., a corpus consisting of originals and translations in two languages (the English Norwegian Parallel Corpus, Johansson and Hofland, 1994). While the main impetus for this project had come from contrastive linguistics, this design turned out to be also well-suited to translation studies.

DTS: Major Corpora and Research Results

In this section, we look at several approaches to corpus-based DTS and discuss the major new hypotheses and insights they have contributed to the field. For the sake of clarity, studies are grouped according to the typologies of corpus resources they employed. The reader should be aware, however, that this is no more than a useful artifice of presentation that

Figure 1 A selection from the English Comparable Corpus (fiction component, Laviosa, 1998).

should not hide the underlying unity of intents and goals as well as the many more or less local differences in corpus design and research methodology.

Monolingual Comparable Corpora (MCC) A monolingual comparable corpus typically consists of two subcorpora of texts in the same language. These are (ideally) similar in all regards except the conditions of production: one subcorpus contains original texts, the other translations. An example of this type of corpus is the English Comparable Corpus (Laviosa-Braithwaite, 1996), developed at UMIST (Manchester). This corpus contains two subcorpora, both in English: one of translated fiction, biographies, newspaper text, and in-flight magazines, the other of comparable original texts in these various subdomains. Figure 1 exemplifies its structure.

Somewhat counterintuitively for the reader who is used to thinking of translation research as an investigation of the relationship holding between a 'source' text (ST) in language A and its translation, or 'target' text (TT), in language B, a monolingual comparable corpus does *not* include the translations' source texts. This follows from the principle, put forward by Baker in 1995, that translation research should undergo a shift of focus, "a shift away from comparing either ST with TT or language A with language B to comparing text production *per se* with translation" (Baker, 1995: 233). The rationale for such a shift is that a comparison of originals and translations along these lines might highlight linguistic patterns in translated texts that differ from those in originals and that are unlikely to result from individual preferences, differences between two language systems, and so on.

Several studies have searched for evidence confirming pre-existing hypotheses on "universal" tendencies or "norms/laws" of translation behavior (Toury, 1995) (*see* **Translation Universals**). Others, taking a more 'corpus-driven' approach (Tognini-Bonelli, 2001), have attempted to identify patterns and to interpret them in terms of (old and) new hypotheses. In what follows, we briefly discuss work related to three such hypotheses, concerning, respectively, *simplification*, *explicitation* (or, more precisely, *explicitness*, [Schmied and Schäffler, 1996]), and (*un*)*typicality* in translation.

Translated Texts Are 'Simpler' Than Originals (Simplification Hypothesis) MCC studies in which this hypothesis – which predates corpus approaches (Blum-Kulka and Levenston, 1983) – was investigated are Laviosa-Braithwaite (1996) and Laviosa (1998). Since the direct observation of shifts between a ST and a TT is not feasible within this approach, this article identifies three features that can be easily searched for and compared across different subcorpora of the English Comparable Corpus (ECC). These

are *sentence length* (the shorter the sentences, the easier the text), *information load* (the fewer the lexical words, the easier the text), and *lexical variety* (the less varied the lexis used, the easier the text). Analyses of the fiction and newspaper subcomponents of the ECC appeared to confirm that translated texts indeed had a lower information load and lower lexical variety than comparable originals. However, while translated newspaper texts in the ECC also featured a significantly lower mean sentence length than their original counterparts, the opposite was true of fiction texts.

Translated Texts Are More 'Explicit' Than Originals (Explicitness Hypothesis) This hypothesis also predates the corpus approach (cf. Blum-Kulka, 1986, on cohesive explicitness in translation). Again making use of the ECC, Olohan and Baker (2000) and Olohan (2001) compared the frequency of (a selection of) optional syntactic elements in originals and translations, the rationale being that the optional explicitation of grammatical relations was likely to result in a more explicit text. Their results highlighted unusually high frequencies of several optional elements in translations as compared with originals. To take just one example from Olohan (2001), translated texts in this corpus clearly favored the pattern 'PROMISE + *that*' over 'PROMISE + *zero*' (*that* is present in 89 out of the total 131 cases), whereas the opposite was true of originals (89 'PROMISE + *zero*' out of the total 135 cases).

Along similar lines, Puurtinen (2004) analyzed the use of explicit clausal connectives (conjunctions, pronouns, adverbs) in a corpus of Finnish children's literature (part of the Corpus of Translated Finnish [Mauranen, 2004]). The corpus contains originals in Finnish and translations from English. It would follow from the explicitness hypothesis that translations should have had a higher frequency of these elements than comparable originals. However, this was not always the case in Puurtinen's data, and results were inconclusive.

Translated Texts Show 'Unusual' Patternings of Typical and Untypical Target Language Features with Respect to Originals ([un]typicality Hypothesis) This hypothesis differs from the previous ones in that it was first developed and investigated within the corpus approach. In this sense, it is truly corpus-driven. It consists of two complementary parts. On the one hand, it predicts that translations will contain patterns that are untypical of the target language (a claim that goes back to Gellerstam (1986) on *translationese*). On the other, it suggests that typical features of the target language that lack obvious linguistic equivalents in the source language will be underrepresented in translation. Work on this hypothesis was carried out by Mauranen (2000), Tirkkonen-Condit (2004), and Eskola (2004), using the Corpus of Translated Finnish. Mauranen (2000: 137) found that a word like *toisaalta* (meaning approximately "on the other hand"), which she described as "highly target-language specific," was much more common in originals than in translations. Similarly, Tirkkonen-Condit (2004) investigated two clitics and a set of Finnish verbs that lack obvious lexicalized equivalents in Indo-European languages. She found that all these elements were underrepresented in translation and showed unusual grammatical and collocational patternings. While those studies were situated toward the lexical end of the lexicogrammatical continuum, Eskola (2004) investigated typical and untypical syntactic structures in a narrative prose subcorpus of the Corpus of Translated Finnish. Findings from this study confirmed those from previous ones with regard to target-language-specific constructions (underrepresented and showing unusual patterning in translation) and further provided evidence of *translationese* (overrepresentation of a source-language typical structure).

Bi- and Multilingual Parallel Corpora (Including Reference Corpora) Bi- and multilingual parallel corpora are collections of originals in language A and their translations in language B (C, D, etc.). While not wholly innovative as a resource for translation research, these corpora differ from single pairs of translated texts inasmuch as (a) they are searchable by means of computerized techniques of analysis, (b) they allow the analyst to abstract away from single texts in an attempt to unveil regularities across a 'representative' body of data (e.g., German literary fiction translated into English, Kenny (2001)), and (c) they may avail themselves of reference corpora of the source and target languages in order to set their analyses against the background of general language use. The aim is, once again, to arrive at generalizations about translation strategies and translation universals/norms/laws. The parallel corpus methodology is sketched in Figure 2.

Issues that have been investigated using this methodology include *sanitization/normalization* (the hypothesis that translated texts are less creative overall than their source texts) and *explicitation/implicitation* (the hypothesis that translated texts are more/less explicit overall than their source texts).

Translated Texts Are Less 'Creative' Than Their Source Texts (Normalization/Sanitization Hypothesis) This hypothesis was investigated by Kenny in

Figure 2 The parallel corpus methodology (exemplificatory data from Danielsson, 2001).

her study based on *Gepcolt*, a corpus of 14 contemporary German novels and their translations into English. Her aim was to find out whether translators "typically draw on more conventional target language resources to replace unconventional [...] lexical features in source language texts" (Kenny, 2001: 111). By isolating instances of lexical creativity in the source corpus with the help of a source-language reference corpus (the Mannheim corpora of the *Institut für deutsche Sprache*, Mannheim) and evaluating the originality of the corresponding target solutions with the help of a target-language reference corpus (the *British National Corpus*), Kenny was able to find evidence of a tendency toward normalization in translation, though she admitted that this was by no means a universal, constant feature.

Translated Texts Are More/Less 'Explicit' Than Their Source Texts (Explicitation Hypothesis) In order to investigate this hypothesis, which is complementary to the 'explicitness' hypothesis, already discussed, researchers have compared source and target texts, looking for evidence of 'explicitating shifts,' i.e., shifts leading to "a rise in the level of cohesive explicitness in the TL text" (Blum-Kulka, 1986: 19). Thus, Øverås (1998) analyzed the first 50 sentences of 20 English novel extracts and their Norwegian translations (from the English Norwegian Parallel Corpus). She looked for such shifts at different rank levels (from word level to clause level) and recorded instances of implicitation shifts, i.e., changes that would result in a more implicit text, thus disconfirming the explicitation hypothesis. This study found confirmation of the explicitation hypothesis (347 explicitating shifts), but the author pointed out that implicitation was also attested (149 implicitation shifts).

Bidirectional Corpora and Mixed Designs As can be seen from the discussion in the previous section, the insights offered by parallel corpora are often complementary to those arrived at through monolingual comparable corpora. Monolingual comparable corpora have provided a new angle from which to look at translated text. But, in the words of Toury (2004: 17), "it is one thing to say that certain regularities were found *in* translation, and something quite different – to claim that the observed regularities were there *because* it is translation." MCC cannot shed any light on the reasons behind the observed patternings. For this reason, a number of studies have taken advantage of *bidirectional*, or *reciprocal*, corpora. These corpora are basically a combination of two parallel corpora assembled according to the same design. Thus, for instance, the pioneering English Norwegian Parallel Corpus used by Øverås (1998) has the structure shown in Figure 3.

Subcomponents A-B and C-D form parallel corpora of English (ST) → Norwegian (TT) and Norwegian (ST) → English (TT), respectively. Since the two corpora were designed so as to be comparable, subcomponents A ↔ D and C ↔ B constitute monolingual comparable corpora of English (O and T) and Norwegian (O and T), respectively. Other combinations are also possible, but they are less relevant to DTS. This corpus design is of particular interest to translation research for two reasons.

First, it allows comparable studies of translation shifts to be carried out in two directions. The study by Øverås (1998) actually consisted of two parts, i.e., the analysis of the first 50 sentences of 20 English novel extracts and their Norwegian translation was complemented with an analysis of 20 Norwegian novel extracts translated into English. Øverås found that the tendency to explicitate/implicitate differed depending on the translation direction: 347 instances of explicitation and 149 instances of implicitation were attested in translation from English into Norwegian, versus 248 instances of explicitation and 76 instances of implicitation in translation from

Figure 3 Structure of a bidirectional corpus (the English-Norwegian Parallel Corpus, Johansson and Hofland, 1994).

Norwegian into English (on language- and direction-specific shifts, see Teich, 2003; also the section 'Recent Developments and Ways Forward').

Second, this corpus design made it possible to check hypotheses made on the basis of MCC against the relevant source texts. Thus, for instance, Pápai (2004) studied explicitation in a small corpus of literary and technical writing that consisted of three subcomponents: (a) originals in English, (b) their translations into Hungarian, and (c) comparable Hungarian originals. Her combined analysis confirmed that explicitness/explicitation is indeed a characteristic feature both of the translation process from English into Hungarian and of the resulting translation product. A similar corpus design was adopted by Puurtinen (1998) in her study of readability and ideology in Finnish original and translated children's literature. Here, the English source texts served as a source of explanation for the unusual patternings observed in translated Finnish with respect to original Finnish.

Other bidirectional corpora currently available are, among others, *Compara* for English/Portuguese (Frankenberg-Garcia and Santos, 2003), the *English Swedish Parallel Corpus* (ESPC, Altenberg and Aijmer, 2000), and the *English German Translation Corpus* (Schmied, 2002).

Limits, Recent Developments, and Ways Forward This summary discussion of corpus-based DTS may give the reader an idea of the vitality of the field. In the 1990s, corpus studies revived interest in the linguistic approach to translation research and produced a host of hypotheses about the nature of translation that will keep researchers occupied for years to come. In more recent years, however, several studies have also pointed to a number of limits and possible pitfalls of this body of work. At the same time, more linguistically informed analyses and new research directions have also been undertaken, in an attempt to both deepen and widen the paradigm. These developments give us high hopes for the future of corpus-based DTS.

Limits A first point worth mentioning with regard to the limits of the corpus-based methodology in translation studies regards the difficulty of maximizing the comparability of the various subcomponents and at the same time ensuring that the corpus is representative of a larger, socioculturally plausible set (e.g., 'children's fiction,' 'popular science articles'). These issues apply to corpus linguistics in general but are crucial for translation research, where the variables to be taken into account when designing the corpus are often doubled with respect to monolingual corpus studies and where the corpora used are typically smaller. Bernardini and Zanettin (2004) provided a more thorough discussion of this point.

Another issue that has been the target of some criticism is the tendency for some studies to draw conclusions based solely on frequency counts of very shallow textual features that can be easily and automatically harvested. Mauranen (2002) discussed differences in the patterns of use of certain Finnish connectors in her monolingual comparable corpus, which may be interpretable in terms of a tendency for translators to adhere to local source text stimuli and/or of a complementary tendency not to adopt 'domesticating' strategies at the level of discourse. These differences are rather subtle and would escape a simple frequency count (i.e., the connectors themselves are neither under- nor over-used in translated vs. original texts but are simply used differently).

A similar criticism was voiced by Teich (2003), who pointed out that methods that rely on simple automatic counts of features (e.g., type-token ratio, ratio of grammatical to lexical words, average sentence length) essentially operate at the level of words. She suggested that "the gap between word counts and [...] explanations lying in the specific cognitive processes involved in translation, is simply too wide. Categories of intermediate levels of linguistic abstraction, such as grammatical or semantic categories, would need to be applied in corpus analysis in order to even have a chance of explanation of the variation found in translation" (Teich, 2003: 22–23).

One last criticism of this approach is possibly some overenthusiasm. Several studies that set out to provide only descriptive evidence about translation did not resist the temptation to draw conclusions not warranted by such evidence. Reflections on the

theoretical and methodological implications of this body of work have recently started to appear. These have suggested that claims about translation 'universals' may be better recast in terms of 'laws' and 'norms' (Toury, 1995) or 'memes' (Chesterman, 1997), given the very partial data on which they are by necessity based and given the difficulties of isolating variables and identifying causes for observed regularities. Toury (2004) warned against the risk of inferring universals directly from regularities that can be spotted automatically while stressing that the identification of causes for observed patterns and behaviors is a weak spot of the corpus approach.

In conclusion, it would seem that if insights into translation universals are to emerge from corpus-based research, they are likely to do so from an accumulation of local studies that are restricted in focus and that control as far as possible the explosion of variables that almost by definition characterize translation. The inclusion in the design of a parallel component is also virtually unavoidable if one is to go beyond mere hypotheses about the motivations behind observed patterns.

Recent Developments and Ways Forward Some recent studies have attempted to go beyond the research designs described in this article, constructing innovative corpus resources and testing alternative methodologies of analysis.

One promising new resource that was recently completed at the University of Oslo is a "multiple translation corpus" (Figure 4). This corpus consists of two English originals (a short story and [part of] an academic paper) and 10 translations of these STs into Norwegian. The translations were commissioned from established professionals who worked independently and handed in a draft and a polished version. The 10 translations and the relative source texts are aligned, thus making it possible to observe the range of variation and the effect of individual strategies, abstracting away from or else contrasting literary vs. technical translation.

There is no denying that the resulting product is an artificial construct that does not resemble anything that could exist in reality. This drawback is unavoidable if one wishes to analyze translations that are (a) contemporary, (b) produced independently of one another, and (c) technical as well as literary. An alternative to this design is the multitarget collection of Hans Christian Andersen's short stories and their English translations, discussed, e.g., in Malmkjær (2003). These translations, spanning more than a century, were likely to have been influenced by previous translations of the same texts. Thus, while they provide a rich source of insights about translation in a diachronic perspective, they are less than ideal when the goal is to control variables as tightly as possible in order to isolate alternative translation strategies and regularities.

Moving on from innovative corpus designs to methodologies, recent attempts have been made to combine existing approaches and/or adapting those from neighboring areas. Kujamäki (2004), for instance, combined classic elicitation tests and corpus-based studies of student translations to shed light on the likely cause of the underrepresentation of target-language-unique items in translation. Learners were asked to back-translate an English or German translation of a text, originally written in Finnish, that contained Finnish culture-specific words (referring to snowdrifts and road conditions) that are not lexicalized in English and German. When translating, the students tended to overlook these equivalents. When prompted by a cloze test in their native language, however, a majority produced them. Thus, by combining cloze tests and translation learner

Figure 4 Structure of the Oslo multiple translation corpus (Johansson, 2003).

corpora (see the section 'Translation Learner Corpora'), Kujamäki was able to provide evidence linking Tirkkonen-Condit's unique items hypothesis (2004) and Toury's (1995) law of interference, which states in rather general terms that a target text surface form is likely to be influenced by its source text surface form.

By drawing on a rich combination of theories and practices – a model of cross-linguistic variation based on systemic-functional linguistics, a contrastive typology of the English and German grammatical systems, bilingual parallel (ST ↔ TT), monolingual comparable (O ↔ T), and bilingual comparable (SL-O ↔ TL-O) analyses of texts – Teich (2003) developed a comprehensive approach to corpus-based translation research. Her aim was to shed light on two apparently conflicting hypotheses: (a) that the source language will 'interfere' with the target text formulation (SL shining through) and (b) that a translation will tend to conform to the properties of the target language (TL normalization). The corpus used for this purpose is a bidirectional collection of German originals with their English translations, and English originals with their German translations (along the lines of the ENPC, see Figure 3). Furthermore, it is register controlled, containing only popular-scientific writing (by experts addressing nonexperts).

Teich found that both shining through and normalization could be observed in translation and that English TTs tended to have more normalization, whereas German TTs were characterized by more shining through. The reasons behind these findings were hypothesized to be related to the differences between the two language systems involved:

> Where the target language has more options in a particular grammatical system, it can afford to let the source language shine through. Where the target language has fewer options [. . .] it has to compensate; where the same compensatory means is used frequently, we encounter TL normalization. (Teich, 2003: 219)

On the methodological side, Teich concluded that an account of normalization could not be provided on the basis of an anaysis of monolingual comparable corpora alone; a contrastive analysis of original comparable texts in two or more languages and an account of their grammatical systems were necessary first steps in order to define a common ground for comparison.

Summing up, there are signs within corpus-aided DTS that the discipline is coming to terms with the complexity of its research object, taking stock of previous studies and work in related disciplines in order to develop more theoretically and methodologically sound approaches.

Corpus-Based ATS: Translation Teaching and Translation Practice

Moving on from translation theory/description to practice, in this section we survey applications of corpora to the teaching of translation (in educational settings), as well as to the practice of translation (in professional settings).

Long before the advent of electronic corpora, translators and translator trainees collected reference texts, in their source and target languages, representative of the subject area/genre of a translation task. The translators read these texts, often called 'parallel texts,' from beginning to end to familiarize themselves with a topic or to search for terms and their translations in authentic contexts of use. Nowadays, bilingual comparable corpora and 'concordancers' (search tools that display a given term or phrase in context) provide a shortcut to sidestep this laborious preparatory work. Large amounts of texts can be searched for terms, expressions, and concepts while a translation is being carried out, allowing even nonexpert translators to produce texts that are terminologically appropriate and that conform to the conventions of the target discourse community. Thanks to these new resources (and in general to the much greater availability of electronic texts), translators can accept a wider range of jobs, including translation into a foreign language (L2).

It is therefore no surprise that corpus use became popular in translator education in the 1990s, with more and more teachers requiring learners to build specialized corpora for their (technical) translation assignments and including corpus construction and use as one of the components of their translation syllabus, on a par with, say, dictionary use and documentation. There is no denying that these developments have been favored by the ease with which single teachers and learners have been able to assemble their own corpora off the Internet.

A number of other uses of corpus tools in the translation classroom have also seen the light, particularly in the area of research into translator trainees' production. Surprisingly, on the other hand, the response of the translation industry has been rather more tepid. Corpus usage has still not reached a consensus among professionals, and this is all the more puzzling if one considers the huge success of other technological aids, which in many respects are not wholly dissimilar – namely, translation memories within computer-aided translation (CAT) tools.

Details of house

Sleeps 2-5

Ground floor: entrance hall, kitchen, pantry, sitting room, dining room.

First floor: 3 bedrooms (1 double, 1 twin and 1 single), bathroom with shower.

Facilities

Fridge, coffee-maker, microwave, kettle, automatic washer, colour TV.

Bed linen and towels are provided.

Sorry no pets or smoking in the house.

Figure 5 An excerpt from a farmhouse vacation online advertisement.

Corpora in the Translation Classroom: Comparable and Parallel Designs

The types of corpora that have been used most often as tools for translation teaching follow either the 'bilingual comparable' or the 'bilingual parallel' design. To these we should add monolingual corpora of the target language, which can assist in the identification of the correct terminology and style/register for a translation. Corpora following this design, however, have a wide range of applications besides translation (e.g., text analysis and LSP teaching), for which reason this article does not specifically focus upon them (but see Figure 8 and Figure 9). As just described, bilingual comparable corpora (or 'comparable corpora' for short) are collections of 'similar' original texts in two languages (dealing with the same topic, belonging to the same genre, produced in the same period, etc.), while bilingual parallel corpora ('parallel corpora') are collections of originals and their translations. Clearly, these types of corpora have different strengths and weaknesses and there are different technical requirements for their analysis. They are accordingly discussed separately.

Comparable Corpora Let us take a concrete example. The description of a vacation farmhouse typically has, after an evocative description of the resort and its beauties, a section with details of the accommodation and the facilities on offer, often structured as a list, as in Figure 5.

Suppose we had to translate this text into Italian. While the context may suggest an interpretation, I would expect the very reduced form of the first statement ('sleeps 2–5') to be confusing for some translator trainees. This use of the verb *sleep* to mean 'have a given number of beds' is indeed attested in dictionaries and has a reasonable number of occurrences in the British National Corpus (25 for the word form *sleeps*). Yet sifting through the evidence may be time-consuming and confusing and may give little or no indication of how typical this use is of the text typology to be translated. A specialized corpus is in this case much more helpful in a learning setting. A search for *sleeps* in an automatically constructed corpus of English farmhouse vacation descriptions (about 1 million words from web pages) yields the concordance lines in Figure 6 (selection).

Figure 6 Selected concordance lines for *sleeps* in a corpus of farmhouse vacation description web pages.

Reading these lines, a learner may get a clearer idea of the meaning of *sleeps* in her or his text, including the fact that the word itself is at the core of a larger frame, quite frequently used in this genre, that takes the form shown in Figure 7.

Clearly, a more accurate search strategy would involve looking for other forms of the verb lemma SLEEP in this context, and we might wish to point this out to our learners. Yet the evidence available is probably enough for this rather trivial point.

We are now left with the problem of finding a contextually appropriate translation for this lexical item. A comparable corpus of Italian farmhouse vacation (*Agriturismo*) descriptions may help. While usually not providing direct translation equivalents, comparable original texts in the target language are likely to express similar notions (the number of guests a vacation house can accommodate probably being a core piece of information these texts are expected to

Figure 8 Selected concordance lines for '*persone*' in a corpus of *Agriturismo* web pages.

convey). In order to find out how this notion is expressed in Italian, we can start by looking for words that are likely to belong to an equivalent lexical item (a method described in detail in Tognini-Bonelli and Manca, 2002). Clearly, *house* or *cottage* would be a poor candidate in this case, as they may appear in many other patterns, and numbers are difficult to search for as a class in a raw text corpus. An alternative would be searching for an Italian equivalent for *people*, i.e., '*persone*'. The concordance lines in Figure 8 are taken from an automatically constructed corpus of Italian *Agriturismo* descriptions (about 600 000 words from web pages).

A possible equivalent for 'sleeps 2-5' might thus be hypothesized to be '*per 2-5 persone*' (literally 'for 2-5 people'). This search strategy would, however, limit our chances of discovering other expressions that are more distant from the English but possibly more current in Italian. An alternative strategy might be to search for possible equivalents of the title 'details of the house,' hypothesizing that the expression we are trying to identify would occur at a similar position in the text in both English and Italian. A search for '*dettagli*' ('details') gives no relevant results, but a search for '*caratteristiche*' ('characteristics') yields the example shown in Figure 9.

The results of a subsequent search for '*posti*' ('places') are shown in Figure 10.

We now have an alternative translation for 'sleeps 2-5', which seems more natural and certainly appears more frequently in the corpus than our first solution ('*per 2-5 persone*'), '*da 2 a 5 posti letto*' (literally 'from 2 to 5 bed places').

Comparable corpora may help trainee translators in their understanding of the meaning and structure of a source text, by drawing attention to both subject matter and genre regularities (and irregularities) across comparable exemplars (Aston, 1999); they also assist a nonexpert translator in the production of a target text that not only is factually correct but also is appropriate to the target genre conventions in terms of register and information structure (even when translating into the L2; see Zanettin (1998) on classroom activities based on comparable corpora).

Parallel Corpora As mentioned in this article, parallel corpora are, at their simplest, collections of originals in one language aligned to their translations in another. Other types of parallel corpora exist, e.g., those consisting of different translations of the same text in the same language (see the section 'Recent Developments and Ways Forward').

The process of alignment consists in the establishment of bonds between units in the texts (usually – for our purposes, at least – at the level of the sentence or of the paragraph) such that a search in one language retrieves the searched word or expression in context, as well as the corresponding unit (sentence or paragraph) in the other language. In order to use a parallel corpus, it is first necessary to align it; this can be done either manually or by using *ad hoc* software programs, some of which are freely available on the

Figure 10 Selected concordance lines for '*posti*' in a corpus of *Agriturismo* web pages.

Web. The corpus can then be searched by means of a parallel concordancer (which may also include its own aligner).

Let us consider an example. The selected concordance lines for the word *paper* (English-Italian) in Figure 11 were obtained using the parallel concordancer ParaConc (Barlow, 1995) on a subset of a freely distributed corpus of EU Parliamentary Proceedings, which comes already aligned and is available in 11 European languages (the corpus was developed by Philip Köhn at the University of Southern California). The search for equivalents was facilitated by the software, which suggests possible candidates, but a degree of post-editing was necessary to arrive at the output shown here. The search word and its translation equivalent are underlined and boldfaced, while relevant collocates are in boldface only.

As can be seen, a parallel concordance gives fast and easy access to a range of possible equivalents for a given word or expression. By showing it in context, the concordance provides information about the more or less set phrases in which it occurs and about the collocations and colligations it forms with other words in texts. Normally, the concordance would also provide an indication of the word or expression's frequency, i.e., whether it appears a few times and/or only in a small number of texts or whether it has wider currency; for obvious reasons of space, this point cannot be exemplified in this article.

From the perspective of terminology, it is important, for instance, to make sure that 'white paper' is translated as '*libro bianco*' (literally 'white book'), the official label for this type of documents, and not as say, 'white document', which would be a more plausible candidate, since a working paper is '*un documento di lavoro*' in Italian, and a policy paper, '*un documento programmatico*'. From the perspective of register and style, it may be interesting for learners to note that the expression 'on paper' has been translated once as 'sulla carta', which is a literal translation, once with the adverb 'formalmente' (*formally*), and once with the semifixed expression 'RIMANERE lettera morta' (*REMAIN a dead letter*), depending on the context.

While evidence from parallel corpora has to be taken with a grain of salt – especially if we are not sure of the quality of the translations in the corpus and/or our learners have yet to develop the necessary critical skills – they clearly make a very useful tool. This is not only because the search for equivalents is far less complex than is the case with comparable corpora but also because they contain problem-solution pairs that are unique to the translation situation and that no comparable corpus could feature.

Pearson (2003) illustrated this point with examples of classroom exercises, using a corpus of *Scientific American* articles and French translations published in the periodical *Pour la Science*. Translating the affiliation of researchers whose work was reported on in these articles is a problem that learners have to solve and for which comparable corpora are of little assistance. A parallel corpus, on the other hand, provides numerous examples. These suggest that when translating the name of a foreign university, translators tend to opt for a name that indicates

where the university is, rather than its official name (e.g., 'State University of New York at Albany' becomes 'L'Université d'Albany').

Other Teaching Applications

Translation Learner Corpora The translation learner corpus, an extension of the parallel paradigm motivated by a growing interest in learner corpora (Granger *et al.*, 2002), is typically a collection of subcorpora, each of which contains multiple translations into the same language of a given text. Like multilingual parallel corpora, translation learner corpora are aligned in order to be searchable. While superficially similar, the two resources are used differently, the emphasis being, in the case of learner corpora, not so much on the observation of professional strategies as on peer-to-peer awareness-raising tasks concerning one's own translation decisions.

The example in Figure 12 is taken from a home assignment for students of translation at the School for Translators and Interpreters of the University of Bologna, Italy. The source text is an article, 'Sustainability,' from Wikipedia, the free online encyclopedia.

Translator trainees sometimes have difficulties thinking of alternative formulations after they have come up with one solution. A corpus of student translations may help in this instance, allowing them to compare their choices with those of their fellow students (and possibly of the teacher or of a professional), educating them to reformulate more and entertain different hypotheses before making a choice. From the teacher's perspective, this corpus may assist when evaluating a student's work: the relative merits of different choices can be compared, and their appropriateness can more easily be shown to be a gradient, going from optimal to unacceptable, rather than a right/wrong question. Furthermore, it may give indications of weak spots shared by large sections of a class, suggesting topics for remedial units.

This type of corpus has a number of advantages: it recycles existing material, copyright is relatively

easy to obtain, and it can be of some use in the translation classroom from early on. The corpus from which the example in Figure 12 is taken, for instance, contains, at the time of writing, only 10 translations of a single text, produced by learners as a home assignment in their first course in translation from English into Italian. Assembling such a corpus may take no more than 2 weeks, and it can then be expanded in several directions: a longitudinal component can be incorporated whereby translations by the same students are added in subsequent years; conditions can be varied, e.g., collecting exam papers on comparable texts, or home assignments on different ones; a system of annotation may also be devised, possibly including an error-tagging system (whereby errors are classified in some way and marked in the corpus, to facilitate retrieval of similar instances). Bowker and Bennison (2003) discussed translation learner corpora in detail, made suggestions about ways of automatizing the process of corpus construction, and gave examples of possible applications.

Building Corpora A number of researchers have pointed out that not only using a corpus but also building one may be a valid learning experience for future language professionals. This is both because constructing 'disposable' specialized corpora (Varantola, 2003) and managing them are perceived to be valuable professional skills in their own right and because a self-constructed corpus is easier to use and to evaluate (Aston, 1999; Maia, 2000). Varantola

(2003) discussed a series of Web-based corpus-construction activities carried out by translation students working in groups on specific projects. She pointed out that the problem was no longer text availability, as was the case before the advent of the World Wide Web, but rather "the relevance, adequacy, reliability and the analysis of this context-sensitive corpus material" (Varantola, 2003: 57). Thus, learners have to develop strategies for sifting through the texts available on the Web to find appropriate, authoritative, congruent texts (style-, register- and content-wise) with respect to a given translation task (note that a careful preliminary ST analysis is thus also required).

Professional Applications

In the previous section, corpus construction and use are introduced as activities that have both a didactic, awareness-raising value and a professionalizing function. Many translation teachers nowadays see corpus management as one of the documentation skills a professional translator requires. As mentioned in the section 'Corpus-Based ATS: Translation Teaching and Translation Practice,' this belief is only partly shared by the translation profession itself, where this still seems to be a niche activity.

In May 2004, I made a posting on the Lantra-L mailing list, that asked professional translators whether they knew or used corpora and concordancing software (I explained what I meant by these two terms) and whether they felt the Web is a more practical alternative these days. Lantra-L is one of the largest mailing lists for discussion of translation and interpreting issues, with, on average, 150 to 200 postings a day. Only five people replied. Their positions can be summarized as follows: (a) I have been using corpora (of English, German, Dutch, French, Czech) (two respondents); (b) I have been using translation memories with more advanced search facilities (one respondent); (c) I have been using corpora, though as a language teacher, not a translator (one respondent); (d) I have been using parallel texts (one respondent). In general, there was agreement that the Web, while useful, does not provide search features flexible enough for the needs of language professionals.

These findings support those of Bowker (2004), who surveyed translation-related job ads and professional association literature in Canada. She found that job ads rarely focused on the ability to use specialized translation software in the first place, and corpus use was never referred to; as for newsletters of professional associations, they tended to focus mainly on translation memories as tools for translators, with few if any references to corpora and concordancers.

In this section we briefly review several areas of relevance to the translation profession in which corpora are (or could be) playing a role.

Computer-Aided Translation (CAT) Systems
Computer-aided translation systems typically include a translation memory manager, i.e., a computer program that creates a database of aligned ST-TT unit pairs as a translation is being carried out. As new ST units are added to the work environment, the translation memory manager compares them with those available in memory and, in case of partial or total matches, presents the user with the corresponding TT unit. Completed translations can also be entered *post hoc* into the translation memory; for this purpose, the package usually includes aligners, which speed up the process of creating matches between units smaller than the text (normally sentences).

The resulting product is superficially very similar to an aligned parallel text, but as we look closer, differences appear. First, a translation memory is normally searched by a computer program, rather than the human end user. Ideally, it should contain units that correspond as closely as possible to each other, because any macroscopic differences (e.g., additions, deletions, gaps) between the ST and the TT are actually detrimental to achieving high levels of match between the two aligned versions. This is not so in parallel corpora, where these differences are meaningful. Second, each unit pair is considered in isolation from the texts to which it belongs. Units may be ordered alphabetically or chronologically, and a user can decide to import only selected units rather than whole texts. Thus, textual features that are above- or cross-sentence level (e.g., aspects of text cohesion or instances of compensation) are impossible to observe. Through parallel corpora and concordancers, on the other hand, users can typically access both one-line concordances and larger contexts (even whole texts) and move between these two levels of analysis. Third, translation memories are by their very nature 'prescriptive' tools that should include only gold standard translations, i.e., translations provided by the commissioner or agency for a specific task, typically previous versions of the same text that need to be updated. Parallel corpora, on the other hand, follow from a more 'descriptive' principle whereby it is suggested that translators may find it useful to check the strategies of fellow translators or acquaint themselves with a given topic or field. It does not follow, however, that they should necessarily adopt the solutions they find in the corpus. Parallel corpora are therefore more adaptable to different tasks, as long as the

end user is aware of their structure, contents, and limitations.

A new generation of tools currently being introduced into the market address the problem of integrating facilities for searching corpora with standard translation memory technology. These 'hybrid' tools (Bowker, 2004) combine the traditional translation memory approach to automatic search and retrieval of perfect and fuzzy matches, and the corpus searching approach. Thus, it is possible for the user to select or type in a word or phrase and retrieve for analysis the matching pairs that contain it. While the search possibilities are still rather crude, these systems would appear to go in the right direction of integrating different approaches to the reuse of existing materials. There is general agreement in the profession that translation memories are useful only for a very restricted set of tasks (basically updates of existing translations) or for very repetitive texts. While corpora take more time to compile and consult, they may be useful in a much wider range of situations, thus justifying a mixed approach.

Terminology Extraction and Management The production of glossaries and terminological databases is an integral part of the translation profession, as well as an area of inquiry and systematization for terminologists. Specialized corpora are a major source of terms, definitions, and context(s) of use, and more and more tools are being developed that assist the translator or terminologist in sifting through corpus evidence in an attempt to identify relevant terms in corpora and produce a profile for them.

In order to extract single- and multiword terms semiautomatically, many different strategies can be adopted. Here we shall limit discussion to two relatively straightforward approaches, one that relies more on statistics and word distributions, the other on linguistic principles. First, a raw-text (untagged) corpus can be searched for words or sequences that are either very frequent or more frequent than average ('average frequency' normally being defined via statistical comparisons with a reference corpus) and/or that are not function words (in the latter case a so-called stop-word list is used that removes function words from the output). A search through a corpus of press releases in the domain of computer hardware, using Wordsmith Tools Keyword facilities (Scott, 1996), and a reference corpus of EU parliamentary proceedings retrieves, among others, the 15 bigram terms in Table 1.

Table 1 Bigram terms in a corpus of hardware press releases[a]

[a]Note that in this case hyphens are treated as word separators.

The second strategy requires that the corpus be part of speech (POS) tagged (by means of an *ad hoc* software program known as a POS tagger (van Halteren, 1999)). In this case, it is possible to search for sequences of parts of speech that follow a given pattern that the terminologist has identified. A list of this type for medical English might include those in Table 2.

Once the terms have been identified in one language, their equivalents have to be found for the other. Parallel and comparable corpora may be of help, as suggested elsewhere in this article. They may also, however, assist in a further way, by facilitating the retrieval of additional information about a term, i.e., a definition and one or more examples of use. While the second step is rather straightforward, at least from the technical point of view, the first is much less so. Automatic routines that retrieve term definitions from unannotated text are not easy to devise. Pearson (2000) suggested heuristics that could facilitate the task, e.g., searching for expressions like 'is a kind of' or 'i.e.'. The corpus used also plays a role, as communication by experts addressing nonexperts might be expected to be richer in terms of definitions than communication by experts addressing other experts. Thus, for these purposes textbooks are probably a better source than research articles.

While corpora are unlikely to replace expert advice, they can go a long way in providing the knowledge required by terminologists and translators to produce databases that take into account the actual use to which terms are put and the phraseology associated with them in real texts. It is likely that more and more CAT tools will include terminology extraction tools that tag texts on the fly, retrieve terms according to user-defined term patterns, provide free-text search facilities for corpus analysis, and facilitate the integration of this information in the compilation of terminological databases.

Table 2 Examples of POS patterns corresponding to English medical terms

Pattern	*Examples*
Noun	*bradycardia, amozicillin, PSG*
Verb	*excise, obtund*
Adjective	*distal, craniofacial*
Noun-Noun	*eye movement, ear oximeter*
Noun-Noun-Noun	*coronary heart disease, oxygen desaturation index*
Noun-Preposition-Noun	*night of monitoring, effect of smoking*
Adjective-Noun	*acoustic rhynometry, circadian rhythm*

Machine Translation Applications The role of corpora in the development of machine translation systems is related only indirectly to the professional concerns of translators, for which reason it will be mentioned here only in passing. In recent years the main thrust of machine translation research has been to integrate 'example-based' and statistical methods with more mainstream, 'rule-based' methods. This new approach relies on large databases of aligned parallel text. In this regard, it follows the same recycling principles as translation memories, but it goes beyond, in the attempt to propose a novel translation rather than simply retrieve existing matching strings. At present, the idea of combining machine translation, translation memory, and corpus searching approaches via hybrid, interactive systems is considered to be one of the ways ahead in this area.

The World Wide Web Thanks to the WWW, translators today have at their fingertips a massive amount of knowledge and textual evidence that can be searched more easily than ever before. An important question to ask therefore is whether corpora are still a valid tool or whether they have become anachronistic.

The advantages of corpora over the Web used as a corpus are numerous. To mention but the first that come to mind, existing Web browsers have not been designed with linguistic applications in mind. Thus, at least for the time being, they offer very crude search facilities. For instance, the world's favorite Web browser, Google, does not distinguish certain spelling variants; therefore, one cannot search for 'thought-provoking' and 'thought provoking' as separate queries. Similarly, specifying a window within which to search for two or more words may be quite demanding. More importantly, the sheer size and diversity of the Web and its changing nature have a number of inevitable consequences. For instance, POS annotation is unlikely to ever be an option (this means, for example, that one cannot search for a given word only when it is a noun). Also, relevant examples from a given domain are typically mixed with irrelevant ones from other domains. Sifting through the evidence may become a lengthy process that one tends to dangerously end as soon as a reasonable hypothesis has formed on the basis of the first few hits returned.

The Web, however, has a series of big advantages over corpora: it is mostly free, is readily available, is familiar, is constantly updated, is very large, and requires no time to design and construct. The last point especially is no small thing when it comes to hard-pressed translators. Attempts have been made to combine the best of two worlds, i.e., either make the Web more like a corpus or speed up corpus construction by using the Web. Several 'Web as corpus' tools have been designed that facilitate linguistically oriented searches (Fletcher, 2004), while experiments have been done in an attempt to automatize as far as possible the search and download of texts from the Web (including parallel texts; Almeida *et al.*, 2002) so as to reduce the time and effort required to build a corpus, and thus hopefully encourage translators to do so.

Baroni and Bernardini (2004) described an algorithm and a suite of freely available Perl scripts that have been developed specifically with professional and trainee translators in mind. These tools (a) find keywords in a text (by comparison with a reference corpus), (b) automatically search the Web for combinations of these words, (c) download texts, (d) convert them from HTML to plain text format, (e) discard duplicates, and (f) extract single- and multiword terms from the newly constructed corpus. This procedure can be iterated as many times as required, and various parameters can be tuned by the user.

Conclusion

In this article I review three major areas at the interface between corpus linguistics and translation, namely, corpus-based approaches to (descriptive/theoretical) translation studies, to translation teaching/learning, and to translation practice. As regards translation studies, I suggest that this research methodology, with its many branches and corpus typologies, is yielding valuable insights concerning translation strategies, norms/laws, and universals. More recently, attempts have been made to go beyond somewhat simplistic early assumptions and methods, to take stock of the new data, and to reflect on their implications. Moving on to the applied perspective, I provide several examples of possible uses of corpora

(parallel, comparable, learner) in the translation classroom and point out that the activity of building a corpus may in itself make a valid exercise in text analysis and documentation. Finally, I consider the role currently played by corpus tools in the translation professions and show it to be still rather marginal, despite an obvious potential, a growing interest, and promising new applications.

Precursors and Pioneers, 1933–1954

Although we might trace the origins of ideas related to machine translation (MT) to 17th-century speculations about universal languages and mechanical dictionaries, it was not until the 20th century that the first practical suggestions could be made, in 1933 with two patents issued in France and Russia to Georges Artsrouni and Petr Trojanskij, respectively. Artsrouni's patent was for a general-purpose machine that could also function as a mechanical multilingual dictionary. Trojanskij's patent, also basically for a mechanical dictionary, went further with detailed proposals for coding and interpreting grammatical functions using 'universal' (Esperanto-based) symbols in a multilingual translation device.

Neither of these precursors was known to Andrew Booth (a British crystallographer) and Warren Weaver

Machine Translation: History

J Hutchins, Norwich, UK

Precursors and Pioneers, 1933–1954

Although we might trace the origins of ideas related to machine translation (MT) to 17th-century speculations about universal languages and mechanical dictionaries, it was not until the 20th century that the first practical suggestions could be made, in 1933 with two patents issued in France and Russia to Georges Artsrouni and Petr Trojanskij, respectively. Artsrouni's patent was for a general-purpose machine that could also function as a mechanical multilingual dictionary. Trojanskij's patent, also basically for a mechanical dictionary, went further with detailed proposals for coding and interpreting grammatical functions using 'universal' (Esperanto-based) symbols in a multilingual translation device.

Neither of these precursors was known to Andrew Booth (a British crystallographer) and Warren Weaver

(a director at the Rockefeller Foundation) when they met in 1946 and 1947 and discussed tentative ideas for using the newly invented computers for translating natural languages. In July 1949, a memorandum by Weaver, which stimulated the start of MT research in the United States, suggested various methods based on his knowledge of cryptography, statistics, information theory, logic, and language universals (Hutchins, 1997).

In June 1952, the first MT conference was convened at MIT by Yehoshua Bar-Hillel, who had been appointed to survey the field. It was already clear that full automation of good-quality translation was a virtual impossibility and that human intervention either before or after computer processes (known from the beginning as pre- and post-editing, respectively) would be essential. Ideas were put forward for normalizing input texts and for microglossaries to reduce ambiguity problems and for some kind of syntactic structure analysis. Suggestions for future activity were proposed; in particular, Léon Dostert from Georgetown University argued for a public demonstration of the feasibility of MT.

Accordingly, he collaborated with IBM on a simple MT system demonstrated in New York on January 7, 1954, with a great deal of media attention. A carefully selected sample of Russian sentences was translated into English using a very restricted vocabulary of 250 words and just six grammar rules. Although the system had little scientific value, its output was sufficiently impressive to stimulate large-scale funding in the United States and to inspire the initiation of MT projects elsewhere, notably in the USSR.

High Expectations, 1954–1966

When MT research began, there was little help to be had from current linguistics. As a consequence, in the 1950s and 1960s, researchers tended to polarize between empirical trial-and-error approaches, often using statistical methods to discover grammatical and lexical regularities that could be applied computationally, and theoretical approaches involving fundamental linguistic research and indeed the beginnings of what was later called computational linguistics (*see* **Computational Linguistics: History**). This decade saw the beginnings of three basic approaches to MT (*see* **Machine Translation: Overview**): (1) the direct translation model, in which programming rules were developed for the translation specifically from one source language (SL) into one particular target language (TL) with a minimal amount of analysis and syntactic reorganization and in which problems of homonymy and ambiguity were simplified by providing single TL equivalents for SL words to cover most senses; (2) the interlingua model (*see* **Machine Translation: Interlingual Methods**), in which translation was into and from some kind of language-neutral representation and that involved complex syntactic and semantic analysis; and (3) the transfer model, in which SL texts were analyzed into disambiguated SL representations and then converted into equivalent TL representations, from which output text was generated.

The direct translation approach was epitomized by research by Erwin Reifler (at the University of Washington, Seattle) and by Gilbert King (at IBM). Large bilingual dictionaries were compiled for a photoscopic store (a purpose-built memory device), in which lexicographic information was used not only for selecting lexical equivalents but also for solving grammatical problems without the use of syntactic analysis. A Russian-English system was installed for the U.S. Air Force, producing translations until the early 1970s – the output was crude and barely intelligible, but appeared to satisfy basic information needs of users.

Dictionary development was also the focus of research at a number of other centers. Anthony Oettinger's group (Harvard University) compiled a massive Russian-English dictionary, both to serve as an aid for translators (a forerunner of the now-common computer-based dictionary aids) and to produce crude word-for-word translations. Sydney Lamb (at the University of California, Berkeley) concentrated on developing maximally efficient dictionary routines and a linguistic theory appropriate for MT – his theory of stratificational grammar.

The system developed at Georgetown University, for many years the largest research group in the United States, was also essentially direct translation in approach, although incorporating various levels of structure analysis: morphological, syntagmatic (noun-adjective agreement, verb government, etc.), and syntactic (subjects and predicates, clause relationships, etc.). Systems installed by Euratom in 1963 and by the U.S. Atomic Energy Commission in 1964 continued in regular use until the late 1970s. A direct translation approach similar to the Georgetown system was made at the Institute of Precision Mechanics (under D.Y. Panov), but with less practical success, primarily because of lack of adequate computer facilities.

Research on interlinguas was almost wholly theoretical. The Cambridge Language Research Unit (Margaret Masterman) investigated a prototype interlingua to produce crude (almost word-for-word) translations, which would be refined by means of the semantic networks of a thesaurus (using mathematical

lattice theory.) Silvio Ceccato (Milan University) developed an interlingua based on cognitive processes, involving the conceptual analysis of words and their possible correlations in texts – a forerunner of the neural networks of later years. Igor A. Mel'čuk (Institute of Linguistics, Moscow) worked on the linguistic foundations of an interlingua, his stratificational dependency (meaning-text) model of language (*see* **Mel'čuk, Igor Aleksandrovic (b.1932)**). Nikolaj Andreev (Leningrad State University) conceived an interlingua as composed of those features statistically most common in a large number of languages.

The transfer approach was epitomized by the research at MIT led by Victor Yngve on syntactic analysis and production, mainly for German and English. Despite Chomsky's association with the group for a short time, transformational grammar (*see* **Generative Grammar**) had little influence – indeed Chomskyan linguistics had little impact on any MT group in this period.

Apart from MIT, the most explicit concentration on syntactic issues was at Harvard (after 1959), where research focused on the predictive syntactic analyzer (originally developed at the National Bureau of Standards under Ida Rhodes), a system for the identification of permissible sequences of grammatical categories (nouns, verbs, adjectives, etc.) and the probabilistic prediction of following categories. However, the results were often unsatisfactory, caused primarily by the enforced selection at every stage of the 'most probable' prediction. (Nevertheless, an improved version, the Multiple-Path Predictive Analyzer, led later to William Woods's familiar Augmented Transition Network parser.)

Computer facilities were frequently inadequate, and much effort was devoted to improving basic hardware (paper tapes, magnetic media, access speeds, etc.) and to devising programming tools suitable for language processing (e.g., COMIT developed at MIT). Some groups were inevitably forced to concentrate on theoretical issues, particularly in Europe and the Soviet Union. For political and military reasons, nearly all U.S. research was for Russian-English translation, and most Soviet research focused on English-Russian systems, although the multilingual policy of the Soviet Union inspired research there on a much wider range of languages than elsewhere.

By the mid-1960s MT research groups had been established in many countries throughout the world, including most European countries (Hungary, Czechoslovakia, Bulgaria, Belgium, Germany, France, etc.), China, Mexico, and Japan. Many of these were short-lived; an exception was the project that begun in 1960 at Grenoble University.

Throughout this period, research on MT became an umbrella for much contemporary work in structural and formal linguistics (particularly in the Soviet Union), semiotics, logical semantics, mathematical linguistics, quantitative linguistics, and nearly all of what is now called computational linguistics and language engineering – and in the Soviet Union with close ties with cybernetics and information theory (Léon, 1997).

The ALPAC Report and Its Consequences

In the 1950s, optimism was high; developments in computing and in formal linguistics, particularly in the area of syntax, seemed to promise great improvements in quality; there were many predictions of fully automatic systems operating within a few years. However, disillusion grew as the complexity of the linguistic problems became more apparent and research seemed to face an apparently insuperable semantic barrier. In an influential survey, Bar-Hillel (1960) criticized the prevailing assumption that the goal of MT research should be the creation of fully automatic high-quality translation (FAHQT) systems producing results indistinguishable from those of human translators. He argued that it was not merely unrealistic, given the current state of linguistic knowledge and computer systems, but impossible in principle.

Although the first working systems (from IBM and Georgetown) were showing that poor-quality translations could be useful in many circumstances, there was growing disappointment at the slow development of good-quality MT. In 1964, the government sponsors of MT in the United States (mainly military and intelligence agencies) asked the National Science Foundation to set up the Automatic Language Processing Advisory Committee (ALPAC) to examine the situation. It concluded that MT was slower, less accurate, and twice as expensive as human translation and that "there is no immediate or predictable prospect of useful machine translation" (ALPAC, 1966: 32). It saw no need for further investment in MT research; instead, it recommended the development of machine aids for translators, such as automatic dictionaries, and the continued support of basic research in computational linguistics. Paradoxically, ALPAC rejected MT because it fell well short of human quality (i.e., it required post-editing) even though human translations are invariably revised before publication and even though the sponsoring bodies were primarily interested in information gathering and analysis, in which lower quality would be acceptable. The influence of ALPAC was profound, bringing virtually to an end MT research in the United States for over a

decade and indirectly bringing to an end much MT research elsewhere. As a consequence, MT was to be no longer the leading area of research in computers and natural language.

The Quiet Decade, 1967–1976

Research did not stop completely, however. Even in the United States, groups continued for a few more years at the University of Texas and at Wayne State University. But there was a change of direction. In the United States, activity had concentrated on English translations of Russian scientific and technical materials. In Canada and Europe, the needs were quite different. The Canadian government's bicultural policy created a demand for English-French (and to a lesser extent French-English) translation beyond the capacity of the translation profession. The demand was even greater within the offices of the European Community for translations of documents from and into all the EC languages.

At Montreal, research began in 1970 on a syntactic transfer system for English-French translation. The TAUM project (Traduction Automatique de l'Université de Montréal) had two major achievements: first, the Q-system formalism for manipulating linguistic strings and trees (later developed as the Prolog programming language) and, second, the Météo system designed specifically for translating the restricted vocabulary and limited syntax (sublanguage) of meteorological reports, which were publicly broadcast from 1976.

Other groups continued with essentially interlingua approaches. In the Soviet Union, Mel'čuk continued his research on a meaning-text model for application in MT. At Grenoble University, Bernard Vauquois developed a pivot language for translating Russian mathematics and physics texts into French – not, however, a full interlingua because it represented only the logical properties of syntactic relationships; there were no interlingual representations for lexical items, which were translated by a bilingual transfer mechanism. A similar model was adopted at the University of Texas (under Winfred Lehmann) in its METAL system for German and English: Sentences were analyzed into 'normal forms', that is, interlingual semantic propositional dependency structures with no interlingual lexical elements.

By the mid-1970s, however, the Grenoble and Texas groups recognized major problems with their interlingua approaches: the rigidity of the levels of analysis (failure at any one stage meant failure to produce any output at all), the inefficiency of parsers (too many partial analyses that had to be filtered out), and in particular loss of information about surface forms of SL input that might be used to guide selection of TL forms and construction of acceptable TL sentence structures. To many at the time it seemed that the less ambitious transfer approach offered better prospects.

The Revival, 1976–1989

In the decade after ALPAC, more MT systems came into operational use and attracted public attention. Most significant were the first Systran installations. Developed by Peter Toma, its oldest version is the Russian-English system at the USAF Foreign Technology Division (Dayton, Ohio) installed in 1970. The Commission of the European Communities installed its first Systran system in 1976 and now has versions for most languages of the European Community (now European Union). Over the years, the original (basically, direct translation) design has been greatly modified, with increased modularity and greater compatibility of the analysis and synthesis components of different versions, permitting cost reductions when developing new language pairs. During the 1980s and subsequently, Systran was also installed at many major companies (e.g., General Motors of Canada, Dornier, and Aérospatiale).

From the early 1980s until the mid-1990s, Systran's main commercial rival was the Logos Corporation. After experience with an English-Vietnamese system for translating aircraft manuals during the 1970s, Logos developed a successful German-English system that first appeared on the market in 1982; during the 1980s, other language pairs were also developed. Also in the 1980s a commercial METAL German-English system appeared, the research at the University of Texas University now funded by Siemens of Munich (Germany). The system was no longer interlingua-based but was now essentially a transfer-based approach. Other language pairs were later marketed for Dutch, French, and Spanish, as well as for English and German.

Research also revived in the late 1970s and early 1980s. In contrast to the focus in the late 1960s and early 1970s on interlingua approaches, this was characterized by the widespread adoption of the three-stage transfer-based approach, predominantly syntax-oriented and founded on the formalization of lexical and grammatical rules influenced by the linguistic theories of the time.

One major exemplar was the system developed at Grenoble (GETA, Groupe d'Etudes pour la Traduction Automatique), the influential Ariane system. Regarded as the paradigm of the second-generation linguistics-based transfer systems, Ariane influenced projects throughout the world in the 1980s.

Of particular note were its flexibility and modularity and its algorithms for manipulating tree representations that incorporated many different levels and types of representation (dependency, phrase structure, and logical). Similar in conception were the multilingual transfer system at Saarbrücken (called SUSY), incorporating a heterogeneity of techniques (phrase structure rules, transformational rules, case grammar and valency frames, dependency grammar, the use of statistical data, etc.), and the Mu system developed at the University of Kyoto under Makoto Nagao, where the most prominent features were the use of case grammar analysis and dependency tree representations. (In 1986, the research prototype was converted to an operational system for use by the Japanese Information Center for Science and Technology for the translation of abstracts.)

One of the best-known projects of the 1980s was the Eurotra project of the European Community, intended as an advanced multilingual transfer system for translation among all the EC languages. Like GETA-Ariane and SUSY, the design combined lexical, logico-syntactic, and semantic information in multilevel interfaces at a high degree of abstractness. No facilities for human assistance during translation processes were envisaged, and problems of the lexicon were also neglected; at the end of the 1980s with no operational system in prospect, the project ended, having, however, achieved its secondary aim of stimulating cross-national research in computational linguistics.

From the mid-1980s, there was a revival of interest in interlingua systems, motivated in part by contemporary research in artificial intelligence and cognitive linguistics. Two major projects were based in the Netherlands. The DLT (Distributed Language Translation) system in Utrecht (under Toon Witkam) was intended as a multilingual interactive system operating over computer networks, in which each terminal was to be a translating machine from and into one language only, using a modified form of Esperanto as an interlingua. The project made a significant effort in the construction of large lexical databases and proposed the use of a Bilingual Knowledge Bank from a corpus of (human) translated texts (anticipating later example-based approaches). The Rosetta project at Eindhoven (under Jan Landsbergen) explored the use of Montague grammar (*see* **Montague Semantics**) – semantic interlingual representations were derived from the interpretation of the derivation trees of syntactic representations – and the feasibility of reversible grammars for analysis and generation. Reversibility subsequently became a feature of many MT projects.

In the latter half of the 1980s, Japan witnessed a substantial increase in activity. Most of the computer companies (Fujitsu, Toshiba, Hitachi, etc.) began to invest large sums into areas that government and industry saw as fundamental to the coming fifth generation of the information society – this included MT. The research, initially greatly influenced by the Mu project at Kyoto University, showed a wide variety of approaches. Although transfer systems predominated, there were also interlingua systems, such as the PIVOT system at NEC and the Japanese-funded multilingual multinational project, with participants from China, Indonesia, Malaysia, and Thailand. There was also considerable commercial activity and most of the computer companies marketed translation software, mainly for the Japanese-English and English-Japanese markets. Many of these systems were low-level direct translation or transfer systems limited to morphological and syntactic analysis and often with little attempt made to automatically resolve lexical ambiguities. Often restricted to specific subject fields (computer science and information technology were popular choices), they relied on substantial human assistance at both the preparatory (pre-editing) and the revision (post-editing) stages.

During the 1980s, many research projects were also established in Korea, in Taiwan, in mainland China, and in Southeast Asia, particularly in Malaysia. There was also an increase in activity in the Soviet Union, where from 1976 research was concentrated at the All-Union Center for Translation in Moscow. Systems for English-Russian and German-Russian translation were developed based on the direct translation approach, but there was also work under the direction of Yurij Apres'jan, based on Mel'čuk's meaning-text model, leading to systems for French-Russian and English-Russian. Apart from this group, however, most activity in the Soviet Union focused on the production of relatively low-level operational systems, often involving the use of statistical analyses (influenced by the Speech Statistics group under Rajmund Piotrovskij at Leningrad State University).

During this period, many researchers believed that quality improvements would come from language research in the context of artificial intelligence (AI; *see* **Natural Language Understanding, Automatic**), such as the investigations by Yorick Wilks on preference semantics and semantic templates and by Roger Schank on expert systems and knowledge-based text understanding. The Japanese investment in artificial intelligence projects also had a major impact and may well have stimulated the revival of government funding in the United States. A number of projects applied

knowledge-based approaches in Japan, in Europe, and particularly in North America. In the United States, the most important was at Carnegie-Mellon University (Pittsburgh) under Jaime Carbonell and Sergei Nirenburg, which experimented with a number of knowledge-based MT systems (Nirenburg *et al.*, 1992).

For syntactic processing, there was a trend toward the adoption of unification and constraint-based formalisms (e.g., Lexical-Functional Grammar, Head-Driven Phrase Structure Grammar; Categorial Grammar, etc.). Complex multilevel representations and large sets of transformation and mapping rules were replaced by lexicalist approaches: monostratal representations, a restricted set of abstract rules, and constraints incorporated into specific lexical entries.

As far as practical use was concerned, one method of improving quality was seen to be the 'control' of vocabulary and syntax. Systems such as Systran, Logos, and METAL were in principle designed for general application, although in practice their dictionaries are adapted for particular subject domains by corporation purchasers. The Xerox Corporation went further by restricting, or controlling, input texts, so that transfer and generation was simpler and there was less need for post-editing. They have been followed by many others in subsequent years – indeed, the design of controlled languages is itself an active area of research (*see* **Controlled Languages**). There have been several companies that design controlled language systems for specific clients (e.g., LANT (later Xplanation) and ESTeam). The major example since the early 1980s has been the Smart Corporation (New York), with customers such as Citicorp, Ford, and the Canadian Department of Employment and Immigration. Restriction to particular subject areas does not necessarily mean controlled input. Special-purpose systems can be designed for particular environments, allowing for less complication in lexicons. The main examples here are the successful Spanish-English (SPANAM) and English-Spanish (ENGSPAN) systems developed during the 1970s and 1980s at the Pan American Health Organization in Washington (under Muriel Vasconcellos).

Developments since 1989

The dominant framework for MT research until the end of the 1980s was essentially based on linguistic rules for syntactic analysis, for lexical transfer, for morphology, and so forth. Since 1989, however, this dominance has been broken by the emergence of new methods and strategies loosely called corpus-based methods.

Most dramatic has been the revival of statistics-based approaches – seen as a return to the empiricism of the first decade as opposed to the rationalism of the later rule-based methods. The two sides, empiricists and rationalists, were first directly confronted at a conference in Montreal in June 1992 (TMI, 1992).

With the success of their stochastic techniques in speech recognition, a group at IBM (Yorktown Heights, New York) developed a statistical MT (SMT) model, Candide (Brown *et al.*, 1990). Its distinctive feature was that no linguistic rules were applied; statistical methods were virtually the sole means of analysis and generation. Candide was applied to the corpus of French and English texts in the reports of Canadian parliamentary debates. The first step was the alignment of SL and TL sentences and words that are potentially translation equivalents. Translation itself was achieved through a translation model (frequency statistics derived from previously aligned SL and TL words and phrases) and a language model of TL word sequences. During the 1990s, statistical methods (*see* **Language Processing: Statistical Methods**) have been the main focus of many research groups, for example, the improvement of bilingual text and word alignment techniques and statistical methods for extracting lexical and terminological data from bilingual corpora. Some have concentrated on the development of purely statistics-based systems, statistical MT (e.g., at the universities of Southern California, Aachen, and Hong Kong), and others have investigated the integration of statistical and traditional rule-based approaches (e.g., at Carnegie-Mellon University; the National Tsing-Hua University, Taiwan; and Microsoft Corporation).

The second major corpus-based approach, benefiting likewise from improved rapid access to large databanks of text corpora, has been what is known as the example-based (or memory-based) approach. Although first proposed in 1981 by Makoto Nagao, it was only toward the end of the 1980s that experiments began, initially in some Japanese groups and during the DLT project. The underlying hypothesis is that translation often involves the finding (or recalling) of analogous examples, that is, how a particular expression or similar phrase has been translated before. Example-based MT (EBMT) involves the matching of input phrases against equivalent or similar SL phrases in a corpus of parallel bilingual texts (aligned either statistically or by traditional rule-based methods), the extraction of TL equivalent or closely matching phrases (using, e.g., semantic networks or lexical frequencies), and – the most difficult process – the 're-combination' of selected TL phrases to produce fluent and grammatical output.

Example-based MT research is pursued actively at a number of Japanese and U.S. centers (Carl and Way, 2003).

Although the main innovations since 1990 have been corpus-based approaches, rule-based research has continued with projects on both transfer and interlingua systems. Examples of transfer systems are the PaTrans system for Danish/English translation of patents (based on Eurotra research) and the LMT system of Michael McCord at IBM. Interlingua-based projects are the CATALYST knowledge-based system at Carnegie-Mellon University for the Caterpillar company and the special-purpose systems (DIPLOMAT) developed for military operations, also at Carnegie-Mellon; the ULTRA system at New Mexico State University (Sergei Nirenburg); the UNITRAN system based on the linguistic theory of Principles and Parameters (*see* **Principles and Parameters Framework of Generative Grammar**) (Bonnie J. Dorr, University of Maryland); the Pangloss project, a collaborative project involving the universities of Southern California, New Mexico State, and Carnegie-Mellon; and the Universal Networking Language project at the Institute of Advanced Studies of the United Nations University (Tokyo), involving groups in some 15 countries.

Another new departure for MT research in the 1990s has been the growing interest in spoken language translation, with the challenge of combining speech recognition and the interpretation and production of conversation and dialog. The first long-standing group was established in 1986 at ATR Interpreting Telecommunications Research Laboratories (Nara, Japan), which has been developing a system for telephone registrations at international conferences and for telephone booking of hotel accommodation (Kurematsu and Morimoto, 1996). Slightly later came the JANUS project (under Alex Waibel) in a consortium of Carnegie-Mellon University, the University of Karlsruhe, and ATR. The JANUS project has also focused on travel planning, but the system is designed to be readily expandable to other domains (Levin *et al*., 2000). Both projects continue. A third shorter-lived group, by SRI (Cambridge, UK) as part of its Core Language project, investigated Swedish-English translation via quasi-logical forms (Rayner *et al*., 2000); and on a larger scale there was a fourth project, Verbmobil (directed by Wolfgang Wahlster), funded from 1993 until 2000 by the German government. Its aim was to develop a transportable aid for face-to-face English-language commercial negotiations by Germans and Japanese not speaking fluent English. Although the basic goal was not achieved, efficient methodologies for dialog and speech translation were developed and the project established top-class research groups in German universities as a valuable by-product (Wahlster, 2000).

Evaluation of MT systems emerged as a major focus of research activity, now recognized as crucial for progress in MT research itself. Since the early 1990s, there have been numerous workshops dedicated specifically to problems of evaluation (often attached to MT conferences), and in particular there has been the series of Language Resources and Evaluation Conferences (LREC). Methodologies developed by the Japan Electronic Industry Development Association (JEIDA) and the Expert Advisory Group on Language Engineering Standards (EAGLES) and for the evaluation of ARPA supported projects have been particularly influential.

The use of MT systems expanded greatly in the 1990s, particularly in commercial agencies, government services, and multinational companies, where translations are produced on a large scale, primarily of technical documentation. This was and remains the major market for the mainframe systems (Systran, Logos, METAL, and ATLAS), now usually on client-server configurations. Already in 1995, it was estimated that over 300 million words a year were being translated by such companies.

The most significant practical development for human translators has been the appearance in the early 1990s of the first translation workstations, which combine various machine aids (*see* **Machine-aided Translation, Methods**): multilingual word processing, OCR facilities, terminology management software, facilities for concordancing (facilities that translators had become familiar with in the 1980s), – and in particular translation memories. The historical origins are described in Hutchins (1998).

Although MT systems for personal computers began to be marketed in the 1980s (e.g., the systems from Weidner, Globalink, and Toshiba), there has been a great expansion since 1990. The increasing computational power and storage capacities of personal computers makes these commercial systems the equal of previous mainframe systems of the 1980s and earlier – and, in many cases, more powerful. However, there has not been a matching improvement in translation quality. Nearly all are based on older transfer-based (or even direct translation) models; few have substantial and well-founded dictionaries; and most attempt to function as general-purpose systems, although most vendors do offer specialist dictionaries. In nearly all cases, systems are sold in three basic versions: systems for large corporations (enterprise systems), usually running

on client-server configurations; systems intended for independent translators (professional systems); and systems for nontranslators (home use).

The Internet has had a major impact since the mid-1990s. First, there has been the appearance of MT software products specifically for translating Web pages and electronic mail messages. Second, beginning in the mid-1990s, many MT vendors have provided Internet-based online translation services for translation on demand – pioneered by Systran on the French Minitel network during the 1980s, by CompuServe in 1995 based on the Transcend system, and then shortly afterward by AltaVista (the Babelfish service using Systran). There are now numerous other online services, some offering post-editing by human translators (revisers), at extra cost, but in most cases presenting unrevised results. Hence, translation quality is often poor, inevitably given the colloquial nature of many source texts, but these services are undoubtedly filling a significant (and apparently widely acceptable) demand for immediate rough translations for information purposes. MT is now reaching a mass market.

Further Reading

The general history of MT is covered by Hutchins (1986), updated by Hutchins (1988, 1993). Basic sources for the early period are Locke and Booth (1955), Edmundson (1961), Booth (1967), Rozencvejg (1974), Henisz-Dostert *et al.* (1979), Bruderer (1982), and Hutchins (2000). For the 1970s and 1980s, there are good descriptions of the main systems in Nirenburg (1987), King (1987), and Slocum (1988). For systems developed during the 1990s, sources include Dorr *et al.* (1999); Somers (2003), the journal *Machine Translation*, the biennial Machine Translation Summit conferences, workshops and other conferences for MT, conferences for language resources and evaluation, computational linguistics, and the Machine Translation Archive.

Introduction

As described in the article on **Machine Translation: Overview**, machine translation (MT) methodologies are commonly categorized as direct, transfer, and interlingual. The methodologies differ in the depth of analysis of the source language and the extent to which they attempt to reach a language-independent representation of meaning or intent between the source and target languages. Interlingual MT typically involves the deepest analysis of the source language.

Figure 1 – the Vauquois triangle (Vauquois, 1968) – illustrates these levels of analysis. Starting with the shallowest level at the bottom, direct transfer is made at the word level. Moving upward through syntactic and semantic transfer approaches, the translation occurs on representations of the source sentence structure and meaning, respectively. Finally, at the interlingual level, the notion of transfer is replaced with a single underlying representation – the interlingua – that represents both the source and target texts simultaneously. Moving up the triangle reduces the amount of work required to traverse the gap between languages, at the cost of increasing the required amount of analysis (to convert the source input into a suitable pretransfer representation) and synthesis (to convert the posttransfer representation into the final target surface form). For example, at the base of the triangle, languages can differ significantly in word order, requiring many permutations to achieve a good translation. However, a syntactic dependency structure expressing the source text may be converted more easily into a dependency structure for the target equivalent because the grammatical relations (subject, object, modifier) may be shared despite word order differences. Going further, a semantic representation (interlingua) for the source language may totally abstract away from the syntax of the language, so that it can be used as the basis for the target language sentence without change.

Comparing the effort required to move up and down the sides of the triangle to the effort to perform transfer, interlingual MT may be more desirable in

Introduction

As described in the article on **Machine Translation: Overview**, machine translation (MT) methodologies are commonly categorized as direct, transfer, and interlingual. The methodologies differ in the depth of analysis of the source language and the extent to which they attempt to reach a language-independent representation of meaning or intent between the source and target languages. Interlingual MT typically involves the deepest analysis of the source language.

Figure 1 – the Vauquois triangle (Vauquois, 1968) – illustrates these levels of analysis. Starting with the shallowest level at the bottom, direct transfer is made at the word level. Moving upward through syntactic and semantic transfer approaches, the translation occurs on representations of the source sentence structure and meaning, respectively. Finally, at the interlingual level, the notion of transfer is replaced with a single underlying representation – the interlingua – that represents both the source and target texts simultaneously. Moving up the triangle reduces the amount of work required to traverse the gap between languages, at the cost of increasing the required amount of analysis (to convert the source input into a suitable pretransfer representation) and synthesis (to convert the posttransfer representation into the final target surface form). For example, at the base of the triangle, languages can differ significantly in word order, requiring many permutations to achieve a good translation. However, a syntactic dependency structure expressing the source text may be converted more easily into a dependency structure for the target equivalent because the grammatical relations (subject, object, modifier) may be shared despite word order differences. Going further, a semantic representation (interlingua) for the source language may totally abstract away from the syntax of the language, so that it can be used as the basis for the target language sentence without change.

Comparing the effort required to move up and down the sides of the triangle to the effort to perform transfer, interlingual MT may be more desirable in

Figure 1 The Vauquois triangle for MT.

some situations than in others. Because in principle an interlingual representation of a sentence contains sufficient information to allow generation in **any** language, the more (and the more different) target languages there are, the more valuable an interlingua becomes. To translate from one source into N target languages, one needs $(1+N)$ steps using an interlingua compared to N steps of transfer (one to each target). But to translate pairwise among all the languages, one needs only $2N$ steps using an interlingua compared to about N^2 with transfer – a significant reduction for the former. In addition, since in theory it is not necessary to consider the properties of any other language during the analysis of the source language or generation of the target language, each analyzer and generator can be built independently by a monolingual development team. Each system developer only needs to be familiar with his/her language and the interlingua.

Another advantage of the interlingua approach is that interlingual representations can be used by NLP systems for other multilingual applications, such as cross-lingual information retrieval, summarization, and question answering (see Figure 2). For example, it is a basic assumption of the Semantic Web that webpages will contain not only source text but also some interlingual representations thereof, against which queries issued in other languages and translated into the interlingua can be matched, and from which various target-language versions of the webpages can be generated. In all of these applications, there is a reduction in computation over approaches that tailor the underlying representation to the idiosyncrasies of each of the input/output languages. Without an interlingual representation, all these multilingual applications require the insertion of a translation step at least once and often in two different places.

Although interlinguas are a topic of recurring interest, only one interlingual MT system has ever been made operational in a commercial setting – KANT (Nyberg and Mitamura, 2000) – and only a handful have actually been taken beyond the stage of a research prototype. Interesting research prototypes are Pangloss (Frederking *et al.*, 1994), CICC, NESPOLE!, and ChinMT (Habash *et al.*, 2003).

Interlingua Definition and Components

An interlingua is a system for representing the meanings and communicative intentions of language. It can be defined as a triple (S,N,L) where:

- S is a collection of representation symbols, often defined in an ontology, where each symbol denotes a particular aspect of meaning or intention (sometimes individually, and sometimes in concert with others according to specific rules of combination).
- N is a notation, within which symbols can be composed into meanings. The rules governing notational well-formedness reflect the compositional derivation of complex meaning out of 'atomic' symbols, an operation that is basic to the theory of the interlingua.
- L is a lexicon, namely a collection of words of a human language such as English, in which each lexical element is associated directly or indirectly with one or more symbols from S. Interlingual MT systems typically include one lexicon for each language.

Figure 2 Use of Interlingua in multiple applications.

An interlingua instance is the representation of the meaning of a given fragment of text, such as a clause, sentence, or document. Such an instance is often written as a list of interconnected nested frame structures, where each proposition in the frame represents some atomic component of the total meaning.

Details and examples of each of these components follow.

Representation Symbols

Typically, an interlingua comprises several kinds of symbols to represent meaning. The largest set can be thought of as the conceptual primitives; rather like the open-class words in a human language, these symbols stand for specific types of objects, events, relations, qualities, etc. Other, smaller, sets of symbols are defined to represent specific fields of meaning, and usually derive from a logical theory about the nature of some phenomenon. For example, the linguistic system of tense can be related to a theory of time, and time can be represented in an interlingua according to a highly formalized subsystem (Reichenbach, 1947; Allen, 1984). Other typical subfields of meaning represent space, causality, the epistemic status of events (actual, hypothetical, desired, etc.), etc.

These symbols are often arranged as taxonomies in which each node stands for a symbol, and information stored at higher-level symbols is inherited downwards and shared by lower ones. The contents and structure of the taxonomy thereby embody, to some degree, the interlingua designer's conceptualization of the world, making the taxonomy an ontology in the classical sense. Although ontologies are as old as Aristotle and are most commonly used in artificial intelligence systems to support complex reasoning, interlingua ontologies form a distinct type: they are generally large (comprising several thousands of symbols), contain relatively little information per symbol, and what information is contained is primarily devoted to interlingua instance composition or linguistic behavior instead of to inference.

It is not uncommon for an interlingual MT system to contain both an upper-level, very general, ontology and then one or more specific domain-oriented ones. The upper ontology contains notions that are shared over all domains in common language; the lower ones encode distinct subworlds, such as finances, sports, chemistry, etc. Usually, the higher-level symbols represent conceptual and linguistic abstractions for which there are no words, and the lower-level ones more concrete meanings for which words exist in the various languages' lexicons. (For example, the Penman Upper Model contains the nodes *NonDecomposableObject* and *DecomposableObject* to separate mass and count nouns.) One advantage of domain partitioning is ambiguity avoidance: the term *bond* in the financial domain has only one meaning, and in the chemistry domain another, enabling the MT system to proceed more expeditiously in each domain.

Ontologies developed for MT include ONTOS (ONTOS, 1989), SENSUS (Knight and Luk, 1994), and Mikrokosmos/OntoSem (Nirenburg and Raskin, 2004). Ontologies developed and used for language technology applications in general include WordNet (Fellbaum, 1998), the Penman Upper Model (Bateman *et al.*, 1989), and Omega (Philpot *et al.*, 2003). Omega can be browsed using the DINO browser.

Notation

The notation is the vehicle by which the symbols' individual shades of meaning are assembled into a complex meaning. The notation is usually instantiated as a network of propositions represented as a set of nested frames, where each proposition employs the symbols of the interlingua, composed according to the specifications of the interlingua in general and of the symbols in particular.

Typically, a frame has a frame header, which may include a frame identifier, and one or more propositions, each being a relation–value pair that links the frame header to the value via the relation. Figure 3 provides an example from the KANT system, representing the meaning of *If the error persists, service is required*. The frame headers – each marked with an asterisk (*) – of the two clauses are BE-PREDICATE and QUALIFYING-EVENT. BE-PREDICATE has two arguments, an attribute and a theme. Each of these is headed by another frame, REQUIRED and SERVICE, respectively. The QUALIFYING-EVENT has a PERSIST event whose theme is ERROR.

In some sophisticated interlinguas, the notation contains separate zones for different kinds of

```
(*BE-PREDICATE
  (attribute
      (*REQUIRED
        (degree positive)))
  (mood declarative
  (predicate-role attribute)
  (punctuation period)
  (qualification
      (*QUALIFYING-EVENT
          (event
              (*PERSIST
                  (argument-class theme)
                  (mood declarative)
                  (tense present)
                  (theme
                      (*ERROR
                          (number (:OR mass singular))
                          (reference definite)))))
              (extent (*CONJ-if))
              (topic +)))
      (tense present)
      (theme
          (*SERVICE
              (number (:OR mass singular))
              (reference no-reference))))
```

Figure 3 KANT representation of *If the error persists, service is required.*

meaning (Nirenburg and Raskin, 2004); typically a zone for world semantics (the conceptual content of the text), a zone for interpersonal semantics (information in the text reflecting the writer, reader, their relationship, etc., which often affects the style of the text rather than the content), and a zone for metatextual information (medium, such as spoken or written; genre, such as telegram, letter, report, article; situation, such as anonymous posting, personal delivery, etc.).

Lexicon

An interlingua lexicon includes information about the nature and behavior of each word in the language. For example, events and actions (usually expressed as verbs) include information about their preferred arguments (agents, patients, instruments, etc.). In some interlinguas, this information may reflect the verbal predilections of one language more than another; for example, *I swim across the river* is expressed in Spanish as *I cross the river swimmingly.* Should the interlingual representation be anchored on *swim* or *cross*? The choice rests with the interlingua symbol set designer. To the degree such asymmetries in the interlingua prefer one language over another, it is said to deviate from true language neutrality. A representation system reflecting one language closely is often called shallow semantics.

Within a chosen representation system, the concepts on which events are anchored are called predicates and the participants in the event are called arguments following the formalism used in logical representations used in artificial intelligence systems. Predicate-argument structure refers to the combination of an event concept and its participants – and a given predicate is said to have a certain number of potential participants – or valency. For example, the verb *load* has a valency of 3: the person doing the loading, the item that is loaded, and the place that the item is loaded.

Table 1 Examples of semantic roles

Role	*Definition*	*Example*
AGENT	An Agent should have the features of volition (able to make a conscious choice), sentience (having perception), causation (able to bring about an effect) and independent existence (existence not resulting from the action)	**John** *broke* the vase
THEME	The Theme is causally affected, or is in a state or changes state, or is in a location or changes location, or comes into or out of existence	John *broke* **the vase**
INSTR	The Instrument has causation but no volition. Typically, an instrument appears with an agent and can be paraphrased with 'using'	John *broke* the vase **with a hammer**

Semantic roles – often called thematic roles – are by far the most common approach to representing the arguments of a predicate semantically. However, the numerous variant theories display little agreement even on terminology. A small set of examples is shown in Table 1.

A number of interlingua researchers have used semantic roles for interlingual MT (Dorr, 2001; Nyberg and Mitamura, 2000). More details are given in 'Interlinguas in Machine Translation' below.

Issues in Interlingua

The notion of interlingua appeals to many, but is a complex undertaking. In this section we examine the issues faced by designers of interlinguas and interlingual MT systems.

Problems with Representing Meaning

Probably the central problem of interlingua design is the complexity of meaning. A great deal has been written about interlinguas, but no clear methodology exists for determining exactly how one should build a true language-neutral meaning representation, if such a thing is possible at all (Hovy and Nirenburg, 1992). It is always possible to add more detail to a meaning representation, but in order to implement an

MT system, the details must end at some point. To date no adequate criteria have been found for deciding when to stop refining the meaning representation, although some preliminary attempts have been made in the NESPOLE! project (Levin *et al.*, 2003) and in the IAMTC project (see 'Interlingual Annotation of Multilingual Text Corpora' below).

A basic design choice is granularity: the number of interlingual representation primitives. The parsimonious approach, exemplified by Conceptual Dependency (Schank and Abelson, 1977), declares that a small number of primitives are enough to compositionally represent all actions. This poses a daunting problem of meaning assembly that has never been seriously attempted. In contrast, the profligate approach, called ontological promiscuity (Hobbs, 1985), essentially allows a representation symbol for every shade of meaning (and certainly one for each lexical item). This poses a problem of representing the essential relatedness of notions such as *buy* and *sell*, *come* and *go*, etc. The ideal seems to have been to aim somewhere in between, seeking conceptual depth and coverage simultaneously. Many researchers (Nirenburg and Raskin, 2004) develop a deep semantic analysis that requires extensive world knowledge; the performance of deep semantic analysis (if required) depends on the (so far unproven) feasibility of representing, collecting, and efficiently storing large amounts of world and domain knowledge. This problem consumes extensive efforts in the broader field of artificial intelligence (Lenat, 1995).

We present an example. What, principally, are the primitive concepts of the meaning representation for *eat*? Do we also need more specific primitives like 'eat-politely' and 'eat-like-a-pig'? This distinction is required to distinguish between the verbs *essen* and *fressen* in German. In general, two strategies are possible. One is to adopt arbitrarily the conceptualizations of one language, and specify the variations of all others in terms thereof; the other is to multiply out all the distinctions found in any language. In the latter case one will obtain two interlingual items representing *eat* (because of German) and two for the object *fish* (because of the distinction between *pez* and *pescado* in Spanish). The situation worsens; in Japanese translation of the verb *wear* depends on where the object is worn, e.g., *head* or *hands*.

Ontologies greatly support the profligate approach, because they allow one to concisely represent systematic relationships between groups of concepts. However, building an ontology remains a problem. For example, the WordNet-based component of the Omega ontology (Philpot *et al.*, 2003) mentioned above contains 110 000 nodes and often provides too many indistinguishable alternatives, whereas the Mikrokosmos-based component of Omega contains only 6000 concepts and does not offer all the concepts needed to represent the full meaning of a word. Thus the word *extremely* contains four concepts in WordNet-based Omega, and each sense is hard to distinguish from the others: (1) to a high degree or extent, favorably or with much respect; (2) to an extreme degree; (3) to an extreme degree, super; and (4) to an extreme degree or extent, exceedingly. On the other hand, the Mikrokosmos-based part of Omega does not contain even one concept for the word *extremely*.

Another issue raised with respect to interlinguas is that, because this representation is purportedly independent of the syntax of the source text, the target text generated reads more like a paraphrase than a strict translation. That is, the style and emphasis of the original text are lost. However, this is not so much a failure of the interlingua as its incompleteness, caused by a lack of understanding of the discourse and pragmatics required to recognize and appropriately reproduce style and emphasis. In fact, in some cases it may be an advantage to ignore the author's style. Moreover, many have argued that, outside the field of artistic texts (poetry and fiction), preservation of the syntactic form of the source text in translation is completely superfluous (Goodman and Nirenburg, 1991; Whitelock, 1989). For example, the passive voice constructions in the two languages may not convey identical meanings. Taken overall, the current state of the art seems to confirm that it is possible to produce interlinguas that are reliably adequate between language groups (e.g., Japanese and Western European) for specialized domains only.

Divergences

An important problem addressed by interlingua approaches is that of structural differences between languages – language divergences – e.g., English *fear* vs. Spanish *tener miedo de*. Some examples from Dorr (1993) are:

- Categorial divergence: the translation of words in one language into words that have different parts of speech in another language. For example, *to be jealous – tener celos* ('to have jealousy').
- Conflational divergence: the translation of two or more words in one language into one word in another language. Examples include *to kick – dar una patada* ('give a kick').
- Structural divergence: the realization of verb arguments in different syntactic configurations in different languages. For example, *to enter the house – entrar en la casa* ('enter in the house').

- Head-swapping divergence: the inversion of a structural dominance relation between two semantically equivalent words when translating from one language to another. For example, *to run in – entrar corriendo* ('enter running').
- Thematic divergence: the realization of verb arguments in syntactic configurations that reflect different thematic to syntactic mapping orders. For example, *I like grapes – me gustan uvas* ('to-me please grapes').

Many divergences are caused by differences in language typology. For example, many verb-serializing languages express the benefactive (e.g., write a letter *for me*) in a serial verb constructions (e.g., write letter *give me*). Some types of meaning are particularly susceptible to divergences. In English, sentences expressing the speech act of suggesting (*How about going* to the conference? *Why not go* to the conference?) cannot be translated literally into most other languages. Divergences are also common in expressions of modality. For example, the expression of deontic modality in *you had better go* in English can be expressed in Japanese roughly as *Itta hoo ga ii*, literally 'go(past form) way/option/alternative subj-marker good' or '(the) option (of) going (is) good.' Some authors have argued that divergences may be the norm rather than the exception (Levin and Nirenburg, 1994).

Resolution of cross-language divergences is an area where the differences in MT architecture are most crucial. Many MT approaches resolve such divergences by means of construction-specific rules that map from the predicate-argument structure of one language into that of another. The interlingua approach to MT takes advantage of the compositionality of basic units of meaning to resolve divergences. For example, the conflational divergence above is resolved by mapping English *kick* into two components, the motional component (movement of the leg) and the manner (a kicking motion) before translating into a language like Spanish.

Interlinguas in Machine Translation

A typical interlingual system is illustrated schematically in Figure 4. Each language requires an analyzer and a synthesizer. The analyzer takes as input a source language sentence and produces as output an interlingual representation of the meaning. The synthesizer takes an interlingual representation of meaning as input and produces one or more sentences with that meaning. In theory, it is not necessary to consider the properties of another language during the analysis of the source language or generation of the target language. To translate from language L_1 to L_2, L_1's analyzer produces an interlingual representation and L_2's synthesizer generates an L_2 sentence with the same meaning.

Figure 4 Interlingual MT system architecture.

Below we illustrate several representative examples of interlingual representations used by developers of interlingual MT systems.

Pangloss

The Pangloss project (Frederking *et al.*, 1994) started as an ambitious attempt to build rich interlingual expressions using humans to augment system analysis. As shown in Figure 5, the representation includes a set of frames representing semantic components (each headed by a unique identifier such as *%proposition_5*) and a separate frame with aspectual information (see *%aspect_5* at bottom) representing duration, telicity, etc. Some modifiers are treated as scalars and represented by numerical values; the phrase *active expansion* is represented in *%expand_1* with an *intensity* of 0.75 (out of 1.0). Note also that all implicit arguments (for instance, the *agent* of *%expand_1*) are explicitly included.

```
%proposition_5
   head            %pursue_1
   time            %time_5
   aspect          %aspect_5
   polarity         positive

%pursue_1
   agent           %company_4
   theme           %policy_1
   purpose         %set up_1
   means           %tie_up_2          ;coreference to %tie-up_1

  %company_4
      name         $"Sezon Group"  ;coreference to %company_3

%policy_1
   policy-type     %expand_1

%expand _1
   agent           %pursue_1.agent
   destination     %overseas
   intensity       0.75

%tie-up_2
   tie-up-partner  %company_5      ;coreference to %company_2

%aspect_5
   phase           continue
   iteration       once
   duration        prolonged
   telicity        false
```

Figure 5 Pangloss interlingual representation of *The Sezon Group will pursue an active overseas expansion policy by means of the tie-up with SAS.*

The focus of the Mikrokosmos project – more recently dubbed OntoSem (Nirenburg and Raskin, 2004) – is to produce semantically rich text-meaning representations (TMRs) of unrestricted text that can be used in a wide variety of applications, including as an interlingua for MT. These representations provide the basis for addressing some of the most difficult problems of NLP, such as disambiguation and all aspects of reference resolution, from reconstructing elliptical utterances to linking textual referents to their real-world 'anchors' in a fact repository.

TMRs (Ontosem's interlingua expressions) use a language-independent metalanguage compatible with that used to represent the underlying static knowledge resources – the ontology and ontologically-linked lexicons. A sample TMR for the input *He asked the UN to authorize the war*, is shown in Figure 6. (Capital letters indicate ontological concepts; the indices represent numbered instances of ontological concepts in the world model built up during this run of the system.) This says that the word *ask* instantiates the 69th instance of the concept REQUEST-ACTION, whose agent is HUMAN-72 (the instantiation of *he*, which was resolved as *Colin Powell* using reference resolution procedures), whose beneficiary is ORGANIZATION-71 (the instantiation of UN, which was resolved to UNITED-NATIONS using reference resolution procedures), and whose theme is ACCEPT-70 (the instantiation of *authorize*, whose theme is WAR-73 – the semantic representation of the meaning of the word *war*). One goal of recent work in the OntoSem environment has been to create TMRs for large amounts of text, populate a fact repository using a subset of information from the TMRs, and then use the fact repository as a language-independent search space for applications such as question answering and knowledge extraction.

```
REQUEST-ACTION-69
  AGENT                HUMAN-72
  THEME                ACCEPT-70
  BENEFICIARY          ORGANIZATION-71
  SOURCE-ROOT-WORD     ask
  TIME                 (<(FIND-ANCHOR-TIME))
ACCEPT-70
  THEME                WAR-73
  THEME-OF             REQUEST-ACTION-69
  SOURCE-ROOT-WORD     authorize
ORGANIZATION-71
  HAS-NAME             UNITED-NATIONS
  BENEFICIARY-OF       REQUEST-ACTION-69
  SOURCE-ROOT-WORD     UN
HUMAN-72
  HAS-NAME             COLIN POWELL
  AGENT-OF             REQUEST-ACTION-69
  SOURCE-ROOT-WORD     he ; ref. resolution has been carried out
WAR-73
  THEME-OF             ACCEPT-70
  SOURCE-ROOT-WORD     war
```

Figure 6 OntoSem interlingual representation of *He asked the UN to authorize the war.*

JapanGloss

The interlingua notation developed for the Japangloss MT system and the Nitrogen generator (Knight and Langkilde, 2000) used symbols from the SENSUS ontology (Knight and Luk, 1994), one of the precursors of Omega. In this notation, frame identifiers are symbols like *h1* and SENSUS symbols are delimited by bars; and in contrast to many other Interlinguas, modality predicates (e.g., likelihood and necessity) are represented as frame predicates, the same way other, normal, actions and events are. Thus in the example given in Figure 7, which represents *It is possible that you must eat chicken* (equivalently, *You might have to eat chicken*), *e4* is the eating by you of the chicken, which by *h2* is obligatory, which in turn by *h1* is possible.

KANT

KANT is the only interlingual MT system that has ever been made operational in a commercial setting. The KANT system (Nyberg and Mitamura, 2000) is a knowledge-based, interlingual machine translation system. KANT is designed for translation of technical documents written in Controlled English to multiple target languages (*see* **Controlled Languages**). The KANT Analyzer produces an interlingua expression for each sentence in the input document; an example appeared earlier in Figure 3. This interlingua is mapped into an appropriate target sentence by the KANT generator. For each target language there is a separate lexicon and grammar.

The KANT system was integrated with the ClearCheck document checking interface (built by Carnegie Group) and deployed in the Caterpillar document workflow during the middle 1990s. The work for Caterpillar involved development of a Caterpillar Technical English (CTE), a corresponding KANT Analyzer, and KANT Generators for French, Spanish, and German. The system delivered to Caterpillar represents the first large-scale deployment of controlled language checking integrated with machine translation. The interlingua used in the KANT system

```
(h1 / |possible<latent|
    :domain (h2/ |obligatory<necessary|
                 :domain (e4 / |eat, take in|
                             :agent you
                             :patient (cl / |poulet|)))
```

Figure 7 Japangloss interlingual representation of *It is possible that you must eat chicken* or *You might have to eat chicken.*

is based on research on the generation of additional target languages, such as Portuguese, Italian, Russian, Chinese, and Turkish.

Interlingual Systems for MT of Spoken Language

The interlingua approach to machine translation has been implemented in several demos and prototypes for translation of spoken language. MT for spoken language begins with speech recognition. The output of the speech recognizer is then passed to the source language analysis module of the MT system. In addition to the problems faced by MT for text, MT for spoken language must deal with disfluencies in speech and imperfect output from a speech recognizer. For this reason, most spoken language MT systems are restricted to task-oriented domains such as travel planning or doctor–patient interviews.

Interlinguas for spoken, task-oriented dialogue typically focus on the dialogue act that the speaker intends to accomplish with his/her utterance. Examples of dialogue acts are suggesting, accepting, and rejecting a time or price. In interlinguas for spoken language, less emphasis is placed on predicate argument structure. The emphasis on speaker intent means that the same interlingual representation will be used for sentences that have very different syntactic structures. For example, the following sentences all carry out the dialogue act of giving information about the price of a room. The concept of costing is expressed by the verb (*cost*) in the first sentence, and the subject (*price*) in the second sentence. In the third sentence, the concept of costing is implicit in the predicate nominal (*one hundred dollars*).

The room costs one hundred dollars per night.
The price of the room is one hundred dollars per night.
The room is one hundred dollars per night.

The JANUS system was the earliest spoken language MT system using an interlingua in the early 1990s (Levin *et al.*, 2000). JANUS was part of the C-STAR consortium (Consortium for Speech Translation Advanced Research), many of whose members adopted the interlingua approach for an international demo in 1999. Other interlingual speech translation systems include Enthusiast, CCLINC, NESPOLE!, Speechalator, Carnegie Mellon University's Thai speech translation system (Schultz *et al.*, 2004), and FAME.

Figure 8 provides an example from the NESPOLE! project, in which both sentences are represented by the given interlingua instance. The NESPOLE! interlingua is based on an annotated corpus of transcribed dialogues in English, German, Italian, and Japanese. It has also been applied to Chinese, Spanish, and French. Its precursor, the C-STAR interlingua, has also been applied to Korean.

Universal Networking Language

The Universal Networking Language (UNL) is a formal language designed for rendering automatic multilingual information exchange (Martins *et al.*, 2000). It is intended to be a cross-linguistic semantic representation of sentence meaning consisting of concepts (e.g., 'cat,' 'sit,' 'on,' or 'mat'), concept relations (e.g., 'agent,' 'place,' or 'object'), and concept predicates (e.g., 'past' or 'definite'). The UNL syntax supports the representation of a hypergraph whose nodes represent Universal Words and whose arcs represent Relation Labels. An example is shown in Figure 9 for the sentence *The cat sat on the mat*.

Several semantic relationships hold between universal words (synonymy, antonymy, hyponymy, hypernymy, meronymy, etc.) which compose the UNL ontology.

Lexical Conceptual Structure

Lexical Conceptual Structure (LCS) is an interlingual representation used as part of a Chinese-English Machine Translation (MT) system, called ChinMT (Habash *et al.*, 2003) that has also been used for many other MT language pairs (e.g., Spanish and Arabic) and other natural language applications (e.g., cross-language information retrieval). The LCS-based approach focuses on the types of divergences described above in 'Divergences.' Consider, for example, the case of a conflational divergence between Arabic and English:

Arabic:	ارسل الصحفي ايميلا الى محطة الجزيرة
Gloss:	'The-reporter sent email to Al-Jazeera'.
English:	The reporter emailed Al-Jazeera.

"I want to know what time the flight leaves Pittsburgh."
"What time does the flight leave Pittsburgh?"

request-information + departure
(time = (clock = question),
transportation-spec = (flight, id = yes),
orgin = name = Pittsburgh)

Figure 8 Two sentences and corresponding interlingua instance from the NESPOLE! Project.

Figure 9 UNL representation of *The cat sat on the mat.*

The LCS representation for this example is shown in Figure 10, glossed as 'The reporter caused the email to go to Al-Jazeera in a sending manner.' Here, the primary components of meaning are the top-level conceptual nodes *cause* and *go*. These are taken together with their arguments, each identified by a semantic role (agent, theme, and goal), and a modifier (manner) *send + ingly*.

Approximate Interlingua

One response to the MT divergence problem (discussed in 'Divergences') is the use of an approximate interlingua (Habash *et al*., 2003). In this approach, the depth of knowledge-based systems is approximated by tapping into the richness of resources in one language (often English) and this information is used to map the source-language (SL) input to the target-language (TL) output.

The focus of the approximate-interlingua approach is to address the types of divergences covered by the LCS-based approach, but with fewer knowledge-intensive components. Thus, a key feature of an approximate interlingua is the coupling of basic argument-structure information with some, but not all, components of the LCS representation. Only the top-level primitives and semantic roles are retained. This new representation provides the basis for generating multiple sentences that are statistically pared down so that the most likely sentence is generated according to the constraints of the TL.

Consider, for example, the conflational divergence example given above ('Lexical Conceptual Structure') between Arabic to English. Figure 11 illustrates the approximate-interlingua approach to translation for this example. The top-level conceptual nodes are first checked for possible matches. Following this, unmatched thematic roles are checked for conflatability, i.e., cases where semantic roles are absorbed into other predicate positions. As long as there is a relation between the conflated argument ($EMAIL_N$) and the new predicate node ($EMAIL_V$), part-of-speech is disregarded.

```
(event cause
    (thing[agent] reporter+)
    (go loc
        thing[theme] email+)
            (path to loc
            (thing email+)
            (position at loc (thing email+) (thing[goal] aljazeera+)))
        (manner send + ingly)))
```

Figure 10 LCS representation of *The reporter emailed Al-Jazeera*.

Annotating Text with Interlingual Information

The success of corpus-based language technology over the past decade has shown the value of systems that automatically learn their processing from large collections of annotated examples. Although no one has yet created an Interlingua-annotated corpus to parallel the 1 million sentences plus syntax trees of the Penn Treebank (Kingsbury *et al*., 2002) (*see* **Treebanks and Tagsets**), several efforts to annotate important parts of an interlingua are underway. Principally, these efforts focus on verbs and their arguments. We list these and then describe one initiative – IAMTC – in more detail to illustrate the issues involved in annotation.

Semantic Annotation Initiatives

WordNet (Fellbaum, 1998) (*see* **WordNet(s)**) provides a terminology taxonomy for English containing over 100 000 terms. Several ontology-building efforts have used this resource as a starting point. Focusing on the creation of wordnets for other languages, the Global WordNet Association lists EuroWordNet, GermaNet, BalkaNet, and many others.

Term taxonomizing and ontologizing efforts include the Chinese HowNet and the Mimida multilingual semantic network.

Focusing on verbs alone, the FrameNet project (Baker *et al*., 1998) is classifying all verbs into groups according to the case roles (thematic roles) they support. The SALSA project parallels FrameNet, working on German verbs. Other FrameNet-related projects are available for Japanese and Spanish.

The PropBank project resembles FrameNet in that it focuses on verbs, but it does not employ a fixed set of case roles, preferring instead a more neutral set of labels with no overall semantics. VerbNet is an associated effort to assign FrameNet-like case roles to verbs. There is a list that combines VerbNet and FrameNet. The NomBank Project closely parallels PropBank, but focuses on nouns (such as nominalized verbs and relational nouns) with argument structure.

The Interlingual Annotation of Multilingual Text Corpora (IAMTC) project is an ambitious attempt to investigate interlingual semantics by annotating and comparing semantic phenomena across six languages. Having prepared bilingual corpora pairing English texts with corresponding text in Japanese, Spanish, Arabic, Hindi, French, and Korean, annotators are assigned to each text impairs to select semantic representation symbols from the Omega ontology

Figure 11 Approximate interlingua for English-Arabic example.

(Philpot *et al.*, 2003) for all nouns, verbs, adjectives, and adverbs. We describe this project in more detail below.

Interlingual Annotation of Multilingual Text Corpora

The IAMTC project has the following goals:

- Development of an interlingual representation framework based on a careful study of text corpora in six languages and their translations into English.
- Development of a methodology for accurately and consistently assigning such representations to texts across languages and across annotators.
- Annotation of a corpus of six multilingual parallel subcorpora, using the agreed-upon interlingual representation.
- Development of semantic annotation tools that serve to facilitate more rapid annotation of texts.
- Design of new metrics and evaluations for the interlingual representations, in order to evaluate the degree of annotator agreement and the granularity of meaning representation.

The IAMTC project is radically different from those annotation projects that have focused on morphology, syntax, or even certain types of semantic content (e.g., for word sense disambiguation). It is most similar to PropBank (Kingsbury *et al.*, 2002) and FrameNet (Baker *et al.*, 1998). However, IAMTC places an emphasis on:

1. a more abstract level of mark-up (interpretation);
2. the assignment of a well-defined meaning representation to concrete texts;
3. issues of a community-wide consistent and accurate annotation of meaning.

The data set consists of six bilingual parallel corpora. Each corpus is made up of 125 source language news articles along with three independently produced translations into English. (The source news articles for each individual language corpus are different from the source articles in the other language corpora.) The source languages are Japanese, Korean, Hindi, Arabic, French, and Spanish. Typically, each article contains between 300 and 400 words (or the equivalent) and thus each corpus has between 150 000 and 200 000 words. The Spanish, French, and Japanese corpora are based on the DARPA's 1994 MT evaluation data. The Arabic corpus is based on LDC's Multiple Translation Arabic, Part 1.

The interlingual representation comprises three levels and incorporates knowledge sources such as the Omega ontology (Philpot *et al.*, 2003) and thematic roles (Dorr, 2001). The three levels of representation are referred to as IL0, IL1, and IL2. The aim is to perform the annotation process incrementally, with each level of representation incorporating additional semantic features and removing existing syntactic ones. IL2 is intended as the interlingual level that abstracts away from (most) syntactic idiosyncrasies of the source language. IL0 and IL1 are intermediate representations that are useful stepping stones for annotating at the next level.

Issues in Interlingual Annotation

A preliminary investigation of intercoder agreement on multiple annotations shows that the more annotators learn the process, the better they become, resulting in an improvement of intercoder agreement (Mitamura *et al.*, 2004). Two assumptions may be made regarding the training of novice annotators in order to improve intercoder agreement. One is that novice annotators may make inconsistent annotations within the same text, but these may be reconciled through a process of intra-annotator consistency checking, in which annotators go over their results to find any inconsistencies within the text. Another assumption is that, if two annotators at the same site discuss their annotation results after their annotation tasks are completed, their judgments may be reconciled through a process of inter-annotator checking, in which each annotator votes, they discuss the differences, and then vote again.

From an MT perspective, issues include evaluating consistency in the use of the annotation language, given that any source text can result in multiple, different, legitimate translations (Farwell and Helmreich, 2003). Along these lines, there is the problem of annotating texts for translation without including in the annotations inferences resulting from the source text. The IAMTC effort described above is the only

initiative, to date, that addresses issues of this type in large-scale annotation of data for use in interlingual MT.

Machine-Aided Translation: Methods

E Macklovitch, University of Montreal, Montreal, Quebec, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The focus of this article is on machine-aided translation (or MAT), with heavy stress on the word *aided*, and we shall begin by distinguishing MAT from machine translation (or MT) pure and simple. Both, of course, seek to automate the translation process through the use of computers, and in both humans generally have an important role to play. In MT, however, the initiative in the translation process is given over to the machine, and the aim is to automate this process completely, eliminating the human's contribution as far as possible. In MAT, on the other hand, the initiative in the translation process remains with the human translator, and the role of the machine is to assist the translator in performing certain tasks – normally, those that can be automated with a good degree of confidence and reliability. The fact that MT systems often do not succeed in automatically producing a high-quality translation – where high quality is indeed a requirement – and that a human must subsequently intervene to postedit or otherwise improve the machine's raw output should not cause us to lose sight of the fundamental distinction between MT and MAT. Whereas MT ultimately seeks to dispense with the human translator, MAT proceeds from the double recognition that, for high-quality translation at least, the contribution of a human translator is generally indispensable, and furthermore, that this situation is not likely to change for the foreseeable future. Why is this? Quite simply because high-quality translation routinely requires a level of understanding that extends well beyond the literal wording of a source text to encompass unpredictable amounts of real-world knowledge, as well as the capacity to reason over that knowledge. Despite the undeniable progress recently achieved by the new empirical methods in machine translation, such knowledge and reasoning capabilities, remain by and large, beyond the ken of today's computers. Hence, where high quality is a *sine qua non* (and not just information scanning,

Machine Translation: Overview

P Isabelle and G Foster, National Research Council of Canada, Gatineau, Quebec, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The term *machine translation* (MT) is used to refer to any process in which a machine performs a translation operation between two ordinary human languages: the *source language* (SL) and the *target language* (TL). This is the sense that appears in the following proposition:

> Machine translation is cheaper than human translation but less reliable.

The term can also designate the product of such a process, as in:

> Reading machine translations is not very pleasant but it is a convenient way to get the gist of foreign-language Web pages.

Finally, machine translation can also refer to the study of methods and techniques that render machines capable of producing (better) translations, as in the title of the present article.

The term applies equally well to written or spoken language, but there is a tendency to prefer the terms *speech translation* or *speech-to-speech translation* for referring specifically to machine translation of spoken language.

Translation is a very effective way of helping people communicate across the linguistic barriers. Unfortunately, human translation is expensive enough that it cannot constitute a practical solution to the everyday needs of ordinary people. As the price of human translation is unlikely to fall substantially, machine translation constitutes our best hope of making translation affordable for all.

The idea of using machines to translate is very old, but it was only around 1950, with the advent of digital computers, that serious work could really start. The initial enthusiasm led many to believe that good-quality machine translation was just around the corner, but they were wrong. After some 50 years of research, we can affirm that, barring an unexpected breakthrough, machines will not be able to compete with human translators in the foreseeable future. This prediction applies not only to difficult material such as literary works, but also to all but the very simplest and repetitive texts (e.g., weather reports).

The present article explains why this is so. We start from a simplistic conception of machine translation and show where it breaks down. Then we show how computational linguists tried to fix the problems through increasingly elaborate approaches. But these more elaborate approaches turn out to raise their own additional problems.

Why Machine Translation Is a Difficult Problem

Let's assume a very naïve theory: translating between human languages is just a matter of looking up the words of the source text in a bilingual dictionary. The next 12 subsections examine the many ways that simplistic theory breaks down and show why translation requires: (a) a fine-grained understanding of the source text; (b) contextual knowledge that makes it possible to fill information gaps between the SL and the TL; and (c) a detailed knowledge of the grammar of the TL.

Segmenting Texts into Words

Before a dictionary search can be performed, the text needs to be segmented into a sequence of individual

words, but ambiguities arise about where exactly word boundaries lie. This problem is most acute in languages that do not place any whitespace between words, like Chinese. We get a good feel for the problem if we remove the spaces from an English text. The string in (1) then gives rise to several alternative segmentations:

(1) Themanywaystowelcome ...
→ The many ways to welcome ...
→ The many ways towel come ...
→ Them any ways to welcome ...
→ Them any ways towel come ...

Segmentation ambiguity is less severe in Western languages, but it still exists. For example, the English string '*in*.' can be segmented either as a single word (the abbreviation of the noun *inch*) or as two words (the preposition *in* followed by a full stop).

Since different segmentations lead to different translations (many of them gibberish), the dictionary lookup procedure needs to be supplemented with a mechanism (maybe based on grammar and semantics) that can select the one segmentation intended by the author of the text.

Dictionary Words versus Word Forms: Morphology

Ordinary dictionaries tend to abstract away from the morphological processes of inflection (*see* → *sees, seeing, saw, seen*), derivation (*convention* → *conventional, conventionalize*, etc), and composition (*twenty-story, engine-driven*) (*see* **Morphology: Overview**). As a result, many of the *word forms* that we observe in a text need to be subjected to morphological processing before they can be looked up in the dictionary.

At least in the case of morphologically-rich languages, MT systems need to incorporate morphological processing. But such processing often gives rise to *morphological ambiguity*. For example, the English form *saw* can be interpreted both as a singular noun and as the past form of a verb. The word form *repair* can belong to the basic verb *repair* with the meaning 'to fix,' but it can also be taken as a derivation on the basic verb *pair* with the meaning 'to pair again.' And the German compound *Staubecken* can be segmented either as the sequence *Stau* + *becken*, in which case it means something like 'reservoir,' or as the sequence *Staub* + *ecken*, in which case it would mean something like 'dusty corners.' These ambiguity problems are similar to those described in the subsection 'Resolving Lexical Ambiguity in the Source Language' below.

Detecting Idioms

Some dictionary words are realized as several text words. For example, in the sentence *John gave up the game*, the string *gave up* needs to be considered as encoding a single *idiomatic* lexical unit because its meaning and translation (in French, the simple word *abandoner*) cannot be predicted from the components *give* and *up* (*see* **Lexicography: Overview; Idioms**).

Moreover, the elements of some idiomatic expressions can be separated by other words, as in the following example:

(2) Some are retaining their old customs but others *gave* them *up* a long time ago.

But the same two words can also appear together without forming an idiomatic expression. Sentence (3), for example, does not contain any instance of the idiom *give up*; rather, it is the sequence *up to* that receives an idiomatic interpretation (in French, *jusqu'à*):

(3) James would give (Max) up to 100 dollars for a good copy of that book.

Thus, an MT system needs to recognize idiomatic expressions, but here too the recognition process is facing ambiguity problems.

Identifying Collocations

The meaning and appropriate translation of a given word is often closely dependent upon the words it co-occurs with, that is, on its *collocations* (*see* **Collocations**). For example, the adverb in *dead serious* and the adjective in *heavy smoker* are used to express intensification rather than to express the basic meanings of these words. Since such collocations are strongly language-dependent, MT systems need to account for them: the correct French translations are not *mort sérieux* and *fumeur lourd*, but rather *sérieux comme un pape* and *gros fumeur*.

Dealing with Unknown Words

Even when we disregard the morphological processes noted in the section 'Dictionary Words versus Word Forms: Morphology', the vocabulary of natural languages is not a closed list. We often meet new proper names in the newspaper, new common nouns in a scientific magazine, etc.

A human translator is usually able to make good guesses about the meaning of a novel word, thanks to her understanding of the context. Using various resources, she will most often be able to find a definition and an appropriate translation. In the worst case, she may have to leave the word itself untranslated but the translation of the rest of the sentence is unlikely to be much affected.

But for an MT system, unknown words are a tough challenge. They tend to jeopardize the system's ability

to understand the structure of the surrounding sentence or phrase.

Resolving Lexical Ambiguity in the Source Language

Even assuming a fixed segmentation and a fixed morphological interpretation, text words often match several different dictionary entries. One reason for this multiplicity is part-of-speech ambiguity. The English word *light*, for instance, can be used either as a noun, an adjective, or a verb, giving rise to a different translation in each case (in French, *lumière, léger*, or *allumer*). Thus an MT system needs to decide on the part-of-speech associated with each particular instance of a word.

But even when their parts of speech are known, words still exhibit *word-sense ambiguity*. Consider for example the verb *replace*; it can mean 'change for a different one' (in French, *remplacer*) or 'put back into place' (in French, *remettre en place*). In this case, the grammatical context can help determine what meaning is intended: when the verb appears with the *subcategorization frame* (that is, pattern of complements – *X replaces Y with Z*, it tends to have the first meaning:

(4) They replaced their old Subaru with a new Volvo.

However, explicit grammatical cues are not always available. Take the word *pen* for example, which can either designate a writing instrument or some kind of enclosure:

(5) Max took his nicest pen and wrote a poem for his mother.
→ Max sortit sa plus belle *plume* et écrivit un poème à sa mère.

(6) Jim placed his little brother in his pen and turned on the TV.
→ Max plaça son petit frère dans son *parc* et alluma la télé.

Nouns like *pen* do not induce any specific subcategorization frames on their environment. So, how can an MT system decide what translation is appropriate in each case?

That ambiguity of the word *pen* was used by Y. Bar-Hillel (1960) to argue against the feasibility of *fully automatic high-quality machine translation*. Linguistic knowledge (lexical, morphological, grammatical, etc.) is clearly not sufficient for choosing the right translations in examples (5) and (6). In such cases, human translators make use of their knowledge of what situations are likely in the real world: people are unlikely to place other people in a writing instrument or to use an enclosure for the purpose of writing. Since Bar-Hillel couldn't see any way to endow machines with such knowledge, he concluded that high-quality MT was impossible. As we will see, other opinions emerged later on.

Resolving Coreference Ambiguity in the Source Language

A different kind of ambiguity has to do with words like pronouns, whose interpretation is strongly dependent on that of a coreferent phrase. Consider the following example:

(7) Squirrels like peanuts. They are good for them.

The second sentence is ambiguous as to which pronoun (*they, them*) refers to which noun (*squirrels, peanuts*). Each interpretation leads to a different translation:

(8a) Les écureuils aiment les cacahuètes. Elles sont bonnes pour eux.
(8b) Les écureuils aiment les cacahuètes. Ils sont bons pour elles.

The first translation conveys the more likely interpretation: peanuts are good for squirrels. Deciding on the right interpretation and translation again hinges upon knowledge of what situations are likely in the real world: people are more likely to claim that peanuts are good for squirrels than to claim that squirrels are good for peanuts.

Structural Divergences

It is often impossible to translate a word without making adjustments to the surrounding grammatical structure, because of various types of *translation divergences* (Dorr, 1990). Consider the following examples in French/English translation:

(9) Dès son lever, Max mange un croissant.
As soon as he gets up, Max eats a croissant.

(10) Anne faillit s'étrangler.
Anne almost choked.

(11) Judy swam across the river.
Judy traversa la rivière à la nage.

The French noun phrase *son lever* needs to be translated as the clause *he gets up* because of a *lexical gap* in English: there is no noun equivalent to *lever*. The French verb *faillir* is translated by the English adverb *almost*, with the result that the main verb of the translation (*choked*) does not correspond to the main verb of the source sentence. Finally, the English manner-of-movement verb *swim* gets translated as a plain movement verb (*traverser*) plus a manner adverbial (*à la nage*).

Structural divergences are very common even between languages that are as closely related as French

and English. As a result, translation equivalences often need to be stated at the level of syntactic patterns rather than at the level of single words.

Word Insertion or Deletion

Contrary to what a naïve dictionary-based model would appear to predict, some words of the SL text can be left untranslated and some words can appear in the TL text that have no counterpart in the source.

The difference can be in 'empty' function words whose presence is required by the grammar of the SL/TL, as for example the *t-il* particle that shows up in the French interrogative:

(12) Has the president seen the results?

(13) Le président a-t-il vu les résultats?

But in other cases, the word to be inserted does carry some meaning of its own. Consider for example the translation of English nominal compounds in a language which, like French, is not so fond of compounding:

(14) oil tank → réservoir à huile

(15) steel tank → réservoir en acier

The choice between the French prepositions *à* and *en* turns out to depend on the implicit semantic relation between the two nouns. The content-to-container relation is usually marked by *à*, while the material-to-artifact relation is rather marked by *en*. Consequently, an MT system needs to figure out what semantic relation binds the terms of a nominal compound.

Another example is the difficult problem of inserting articles in Chinese-to-English translation (there are no articles in Chinese).

Language-dependent Explicitation Constraints

Languages differ a lot on *what they force their speakers to make explicit*. Consider for example the difference between languages that have a grammatical gender system (like French) and those that do not (like English). In translating sentence (16) into French, the need arises to choose between two possibilities:

(16) Jack has invited one of his students for dinner.
→ Jack a invité *un* de ses étudi*ants* à dîner.
→ Jack a invité *une* de ses étudi*antes* à dîner.

The first translation is for a male student, the second for a female student. French makes it impossible (or at least awkward) not to disclose the gender of the student. The relevant information is just not available anywhere in sentence (16). It may be available from the rest of the text, but extracting it will generally require a capability to reason on the situations being described in there.

Grammatically-marked politeness forms provide another example of explicitation constraints. For example, when a human translator translates an English dialogue into French, person A's *you* to person B will be translated as *tu* or *vous* depending on the translator's assessment of the social and personal relationship between A and B. A more extreme example will be found in the elaborate system of *honorifics* of the Japanese language.

Differences in lexical structures can also force the translator into making extra information explicit. Consider for example the problem of translating the following sentence into French:

(17) He decided to cut Milou's hair.

French has no word that means exactly the same as *hair*. Rather, it forces users to choose between *poils* (for animal hair and for human body hair) and *cheveux* (for human head hair). Again, the relevant information is not available locally and a human translator will resort to her global understanding of the situations described in the text. For example, the text might make it clear that Milou is a person but say nothing more about what kind of hair is to be cut. In that case, the translator might well choose *cheveux* on the basis of her knowledge that it is more customary for people to have their head hair than their body hair cut by other people.

Target-language Grammar

The choice of a correct TL equivalent often depends on the grammatical context of the TL. An obvious example is the fact that the translation of English determiner *the* as *la*, *le*, *les*, etc., depends on the French noun modified by that determiner. We saw a similar case in discussing the possible translations for utterance (8): in the more likely interpretation of that utterance, the pronoun *they* gets translated as *elles* because its antecedent *in the French text* is the feminine plural noun *cacahuètes*.

Another example of the importance of the grammatical context in the TL is the interdependence between the choice of the translations for a verb and for the elements that appear within its syntactic frame. For example, the English verb *know* translates into French as *connaître* or *savoir* depending on whether the direct object *in French* is a noun phrase or a clause. There are cases where both translations are possible:

(18) John knows that Mary is angry.
→ John sait que Mary est en colère.
→ John connaît la colère de Mary.

Word Order

Another obvious failure of a dictionary-only approach is that it cannot account for the necessity to place words in a different order when going to a different language. In general, ordering rules apply not to single words but rather to whole phrases based on their grammatical function (*see* **Word Order and Linearization**). For example, in German subordinate clauses, the verb needs to be placed after its object:

An MT system clearly needs to understand the grammatical structure of the SL and TL sentences in order to produce the correct word order.

Rule-Based Approaches: Towards More Abstraction

Rule-based approaches to MT can be characterized according to the level of abstraction at which the passage from the SL to the TL is attempted. The space of possibilities is often schematized as the 'Vauquois triangle,' illustrated in Figure 1 (Vauquois, 1968). At the bottom of the triangle stands the *direct approach* in which the TL text is produced by applying translation rules directly to the SL text. In the *transfer approach*, translation rules are applied to abstract language-dependent intermediate representations (IR) that are connected to the source/target texts through analysis/generation rules. In the *interlingua approach*, the analysis and generation processes connect the source and target text with a shared language-independent meaning representation.

Figure 1 Vauquois triangle.

Direct Systems and Morphology-based Translation

The pure dictionary lookup approach discussed above amounts to an extreme form of the direct architecture. Even the earliest practitioners of MT realized that something more was needed. Rule-based morphological analysis was soon introduced in order to deal with inflections in morphologically rich languages. This analysis step remains a standard feature of modern MT systems, often implemented through the use of *finite-state networks*. It was also recognized from the start that additional rule systems are required: (a) for selecting among the various possible translations of each word; and (b) for reordering the words of the TL.

In early systems such as the Georgetown-IBM prototype that gave rise in 1954 to the first public MT demo MT (Garvin, 1967), the rules could only operate on a strictly local context (e.g., a three-word window). But later systems were designed to handle a more general context. In so doing, they adopted at least in part the idea of a separate analysis step, thereby blurring the distinction between direct and transfer systems (this can be traced at least as far back as (Zarechnak, 1959)). Over time, the direct approach was refined to the point where it could give rise to commercial systems such as SYSTRAN and SPANAM, that remain to this day among the best existing MT systems.

The better direct systems manage to tackle reasonably well many problems of text segmentation, morphology, idioms, lexical ambiguity, collocations, word insertion/deletion, and word order. But since they still rely on shallow and local grammatical analyses, they are unable to guarantee the grammatical coherence of their output. Moreover, in the absence of suitable semantic and pragmatic models, their treatment of ambiguities is based on various *heuristics* (that is, rules-of-thumb), including a rather massive use of phrases in the dictionary. When the heuristics break down, the target text often becomes semantically and/or pragmatically incoherent.

Transfer-based Systems

The transfer architecture was first proposed by Yngve (1957) and is illustrated in Figure 2.

There are three important ideas in this architecture:

1. SL/TL equivalences are stated at the level of abstract representations of the texts;
2. The overall process is separated into three distinct steps: (a) analysis, which builds an abstract representation of the SL text; (b) transfer, which maps that SL representation onto an equivalent

one for the TL; and (c) generation, which produces the TL sentence from the TL representation; and

3. Linguistic data (dictionaries, grammars) is separated from the algorithms (programs) that manipulate them. Rather than directly writing an *ad hoc* computer program for sentence analysis, one writes abstract (language-specific) grammar rules in a linguistically perspicuous metalanguage such as *augmented context-free grammars*, then a general-purpose (language-independent) parsing algorithm is used for applying the grammar rules to the input text.

This modular architecture facilitates the reuse of the same algorithms and the same linguistic data in a variety of different tasks.

The nature of intermediate representations is variable, but most systems use something at least as abstract as sentence-level Chomskyan syntactic tree structures. A SL sentence such as *The hungry lion saw the lamb*. might receive a representation like that of Figure 3.

Rules of *lexical transfer* and rules of *structural transfer* are then applied to this SL tree representation to derive an equivalent one for the TL. The statement of correspondences is facilitated by the fact that many of the obstacles described in the section 'Why Machine Translation Is a Difficult Problem' have been removed: word segmentation is explicit, words are morphologically analyzed and their parts of speech are made explicit, the phrasal structure is shown, etc.

Lexical transfer rules can refer to various features of the context. For example, the rules of Figure 4 translate the word *light* with reference to its part-of-speech assignment and the verb *replace* with reference to its subcategorization pattern (see discussion about sentence (4) above). It is also possible to handle many idiomatic expressions in a similar way: a subtree that matches the SL expression is mapped *en bloc* onto a semantically equivalent subtree of the TL. Structural transfer rules are used for handling grammatical differences such as word order.

The subsection 'Target-language Grammar' above noted that the statement of translation equivalences was often complicated by issues of TL grammar such as morpho-syntactic agreement. But the use of abstract intermediate representations alleviates this problem too by making it possible to state correspondences only at the level of canonical forms (e.g., THE → LE). The connection between the canonical form and its appropriate surface realization (e.g., *le, la, les, l'*) is handled by the language-specific grammar rules of the analysis and generation components.

As suggested by the Vauquois triangle, intermediate representations can be made more abstract. For example, they can be akin to the *deep structures* of Chomsky's transformational grammar and its descendants (HPSG, LFG, etc., – *see* **Head-Driven Phrase Structure Grammar; Lexical Functional Grammar**). With such an approach the two sentences of (19) will have similar deep representations in which *their old Subaru* is the *deep object*, with the result that the translation rule of Figure 4 will cover the case of the passive sentence as well:

(19) They replaced their old Subaru with a new Volvo.
Their old Subaru was replaced with a new Volvo.

Going further in the direction of a *semantic transfer*, intermediate structures can also feature a normalized lexicon. For example, synonym words can be mapped onto a unique representative of the class. Mel'čuk and Zolkovsky's (1970) *lexical functions* are sometimes used as a general framework for lexical normalization. This framework provides a treatment for some language-specific collocations (cf. the subsection 'Collocations' above). For example, the notion of 'intensification' can be represented by an abstract semantic element *Magn* common to the intermediate representations of both languages (the creation and use of such elements constitutes a small step in the direction of the language-neutral interlinguas discussed below):

Figure 2 The transfer architecture.

Figure 3 Syntax-based intermediate representation.

Figure 4 Lexical transfer rules.

(20) Source text: *heavy smoker*
→ English IR: Magn(smoker)
→ French IR: Magn(fumeur)
→ French text: gros fumeur

Many transfer-based systems have been developed over the years. Some classical examples are:

- ARIANE (Vauquois and Boitet, 1985)
- TAUM-AVIATION (Isabelle and Bourbeau, 1985)
- EUROTRA (Allegranza *et al.*, 1991)
- METAL (Slocum, 1987)
- LMC (McCord, 1989)

METAL and LMC have given rise to commercial systems: Lantworks for the first one and Linguatec and Websphere Translation Server for the second one.

Transfer-based systems are in principle capable of attacking many problems that are out of the reach of direct systems. However, their much more ambitious analysis and generation processes increase the risk of processing errors. As a case in point, syntactic parsing tends to get into trouble in the face of highly complex sentences, ill-formed ones, and unknown words. A failed parsing process will then result in missing or unpredictable output. Second, syntactic ambiguity tends to lead to a proliferation of alternative analyses. The following sentence pairs illustrate ambiguities with respect to adjective attachment (either to the next noun or to the rest of the noun phrase) and prepositional phrase attachment (either to the noun phrase or to the verb phrase).

(21a) He bought liquid oxygen tanks.
(21b) He bought rusted oxygen tanks.

(22a) He killed the girl with the red dress.
(22b) He killed the girl with the revolver.

Transfer-based systems are better at uncovering such ambiguities (based on syntactic processing) than at resolving them (which requires semantic and knowledge-based processing). In other words, they tend to ask more semantic questions than they have answers for. This inability may be why, in spite of their theoretical advantages, they have not thus far managed to consistently outperform advanced direct systems like SYSTRAN.

Interlingua and Knowledge-based Systems

An extensive survey of interlingual methods will be found in a companion article (*see* **Machine Translation: Interlingual Methods**). This article provides just an overview of some of the basic issues.

Language-independent Representations In MT, the term 'interlingua' is used to designate any artificial language intended to serve as a language-independent intermediate representation between SL and TL texts. An interlingua normalizes the way meanings are expressed not only within a given language (as in deep transfer systems) but also across all languages.

In the interlingual architecture, the analysis and generation components perform mappings between the source and target texts and their shared interlingua representation. Since no transfer is required, an interlingual system translates in all directions between n languages using only $2n$ components (n analyzers plus n generators). By contrast, the standard transfer architecture requires n analyzers and n generators, plus no less than $n \times (n-1)$ pair-specific transfer components. For the 20 current official languages of the European Union, such a system would require 380 different transfer components!

While this example is often invoked as a strong argument in favor of the interlingua architecture, it should be observed that in the transfer approach most pair-specific components can be eliminated by channeling all translations through one particular language-specific IR that is used as an arbitrary 'pivot.' This results in a *double-transfer approach* that we illustrate in Figure 5, for the example of French-to-German translation through an English-oriented pivot representation. This architecture only requires n analyzers, $n-1$ X-to-pivot transfer modules, $n-1$ pivot-to-Y transfer modules, and n generators.

Figure 5 Double-transfer approach.

Moreover, it can be argued that these remaining $2(n-1)$ transfer modules have their hidden counterparts in any interlingua system. Each interlingua-oriented analyzer needs to perform both: (a) a source-language specific analysis such as syntactic parsing; and (b) a mapping from the SL/TL vocabulary and structures and those of the interlingua. And each interlingua-oriented generation component also has such a double structure. Consequently, it can be argued (perhaps controversially) that the double-transfer and interlingua architecture are not really different. Whether or not we use the term 'transfer' to designate a map from language-specific structures onto an artificial interlingua is mostly a terminological issue.

One potential advantage of a language-independent interlingua has to do with language-specific explicitation constraints (see the subsection 'Language-specific Explicitation Constraints' above). The language-specific representations of the double-transfer approach will lack various pieces of information that are needed for generating texts in other languages. For example, an English-oriented representation will lack information about the gender of people referred to by common names (see example (16)). Interlinguas, by contrast, are meant to make explicit any piece of semantic information that is required in at least one of the TLs.

However, summing over all language-specific requirements has at least two important drawbacks: (a) since languages often classify the same semantic objects along different axes, the consequent need for cross-classification may lead to severe inflation in the size of the required interlingua vocabulary; and (b) if an interlingua system comes to be used just for translating between a single pair of languages, a lot of its effort will be wasted on eliciting irrelevant information. The transfer approach is not susceptible to the cross-classification problem; and it can be organized so as to perform 'lazy explicitation' by linking specific explicitation operations with specific transfer modules. For example, the search for indicators of the social relationships that determine the choice between *tu* and *vous* could be triggered by the English-to-French transfer.

Another attribute that is sometimes conferred upon interlinguas is that of 'language neutrality,' but it is not entirely clear what that means. For example, given structural divergences (cf. the subsection Structural Divergences above) such as the following one between English and French:

(23) John ran across the Paris.
→ John traversa Paris à la course.

Should the interlingua opt for a third (neutral) way of expressing the same content? What would be gained by doing that? In practice, language neutrality is seldom really maintained, because interlingua designers tend to make extensive use of the vocabulary and structures of one specific language as a starting point. Since the starting language is most often English, several interlinguas have been criticized for being merely 'English with capital letters,' which makes the similarity with the double-transfer approach discussed above even more obvious.

The Knowledge-based Approach Transfer-based approaches have historically relied mostly on *linguistic* descriptions of the morphological, syntactic, and lexical structures of pairs of natural languages. The interlingua architecture, on the other hand, has often been coupled with a more *knowledge-based* approach. This approach emphasizes the representation and use of general knowledge as practiced in artificial intelligence (AI).

The previous section 'Why Machine Translation Is a Difficult Problem' discussed several examples where a translation decision involves the use of extra-linguistic knowledge (e.g., disambiguating the meaning of the word *pen* in examples (5) and (6) or determining the reference of the pronouns in example (8)). In the 1970s and 1980s, researchers in the field of artificial intelligence set out to develop formalisms that would make it possible: (a) to encode the meaning of the text in a language-independent way; (b) to encode large amounts of extra-linguistic knowledge; and (c) to reason about that knowledge in order to bring out pieces of information needed for resolving particular translation problems.

Many different representation formalisms were proposed based on semantic networks, on frames (Minsky, 1975), on various logics (Nilsson, 1991), etc. Schank (1975) introduced a language called Conceptual Dependency in which natural language verbs were analyzed in terms of a small number of conceptual primitives that would help capture some kinds of inferences. Schank and Abelson (1977) introduced an interesting abstraction called a *script*,

which is meant to capture institutionalized behavior patterns, such as the stereotyped sequence of events that is expected when eating in a restaurant: you walk in, a hostess takes you to a table where you sit, the waiter brings a menu, takes your order, etc. Now, consider the problem of translating the following sentence:

(24) He brought the check.

In isolation, the word *check* is ambiguous between: (a) a written order instructing a bank to pay money (in French, *chèque*); and (b) a slip indicating what amount is due (in French, *l'addition*). But when sentence (24) is part of a story about people eating in a restaurant and *he* is taken to refer to the waiter, meaning (b) will automatically be selected because the restaurant script creates an expectation that a waiter will be bringing a payment-requesting slip, but no expectation that he will be paying the clients.

While such knowledge-based solutions appear intuitively plausible and appealing, they have proven impossible thus far to implement on a real-life scale. Common-sense reasoning is still very poorly understood and the amount of world knowledge required to support general-purpose intelligent reasoning is staggering. As a result, the hard-core knowledge-based approach has only produced toy MT systems.

More recent work on knowledge-based MT has tended to deemphasize the general-purpose reasoning capabilities and to focus more on the organization of the natural language concepts into an interlinguistic ontology (Nirenburg and Raskin, 2004). Examples of such systems include KBMT-89 (Nirenburg, 1989) and PANGLOSS (Nirenburg, 1994).

The KANT system (Nyberg and Mitamura, 1996) is one of the rare knowledge-based systems that has been scaled up and put into real-life use. However, KANT is quite restricted because: (a) it is designed to work with controlled input; and (b) it translates from a single source language only (English), which appears to mitigate the significance of using an interlingua.

It appears safe to conclude that in rule-based MT, the trend towards more-abstract representations has not been very successful from the applications point of view. The processes needed to create such representations turn out to be difficult and error-prone enough to jeopardize the benefits of the approach.

Corpus-based Approaches

Overview

Corpus-based MT systems rely on translation rules that are learned automatically from examples of human translations. Very often these rules are statistical, for instance giving the probability that *femme* in French will translate into *woman* in English. This approach to automatic translation has become increasingly popular in recent years, especially among research systems. In a recent (2004) evaluation of MT performance conducted by the American National Institute for Standards and Technology (NIST), a large majority of the participating systems were corpus-based.

The crucial resource for corpus-based MT is a *parallel corpus*: a collection of documents that exist in both the SL and the TL, on which the system can be trained and tested. Although much less abundant than monolingual corpora, such bilingual (and even multilingual) corpora are becoming available in increasing size for an increasing number of language pairs. Notable examples of parallel corpora are the Canadian Hansard (an English/French corpus of parliamentary proceedings) and the NIST evaluation corpus (Arabic/English and Chinese/English); both are available from the Linguistic Data Consortium.

Parallel corpora typically come in the form of translated document pairs. A first step in virtually all learning approaches is *sentence alignment*, in which correspondences at the sentence level are made explicit. The output from this process is a sequence of *segment* pairs in which each half is a single sentence except in cases where no one-to-one sentence correspondence exists, as shown in Figure 6. Sentence alignment poses a chicken-and-egg problem: it is a necessary prerequisite to effective strategies for learning how to translate, but it requires some translation knowledge in order to be performed accurately. Fortunately, due to the coarse-grained nature of the problem, relatively crude methods such as comparing sentence lengths (Gale and Church, 1992) and matching similar-looking words across languages (Simard *et al.*, 1992) yield good results. Alignment accuracies vary widely across different corpora, but are frequently above 95%.

A straightforward way to translate using an aligned corpus would be to seek exact matches for source sentences, then output the corresponding translations. This exercise would guarantee a reasonable translation for any new sentence that was found verbatim in the corpus. However, for all but the shortest sentences, the odds of finding an exact match would be almost nil, even in an enormous parallel corpus (barring repeated texts, which are the basis for the *translation memories* described in the subsection 'Example-based Machine Translation'). At the other end of the spectrum from a sentence-matching approach is a word-matching strategy in which individual source words are replaced by translations inferred

I was there, along with a hundred of his friends. We were there not only to bid him goodbye but also to salute his life.	J'étais présent, ainsi qu'une centaine de ses amis pour lui dire au revoir, oui, mais aussi pour saluer sa vie.
Èmile Benoit was widely known for his folk music, his *joie de vivre*, his sense of humor and his generosity.	Le monde a connu Émile Benoit pour sa musique folklorique. Sa joie de vivre, son sens de l'humour et son grand coeur sont également ses marques de commerce.
Whether in Quebec city for the summer festival or in St. John's to be awarded an honorary doctorate, he always managed to spread his zest for living.	Qu'il ait été à Québec pour le festival d'été ou à Saint-Jean pour recevoir son doctorat honorifique, il demeurait toujours la même personne qui répandait sa joie sur tous.

Figure 6 Example of non–one-to-one sentence alignments: in the top row, two English sentences translate to a single French sentence; in the middle row, one English sentence translates to two French sentences. The bottom row illustrates a regular one-to-one correspondence.

from the training corpus. This strategy would have all the problems described in the section 'Why Machine Translation Is a Difficult Problem' above – and more – but it would also have the benefit of producing at least *some* output for any source sentence.

Real corpus-based systems are of course more sophisticated than this, but the sentence-to-word spectrum illustrates a fundamental tradeoff in their design: extracting more information from the training corpus (e.g., using sentence matching or some more refined technique) can lead to better performance, but carries the risk of placing too much emphasis on details that are specific to that corpus. This fundamental difficulty is in fact inherent in *any* attempt to learn from data, and it is known as the *bias-variance tradeoff* in the field of machine learning. It can be alleviated to some extent by using larger and more representative training materials, but even the largest available corpora encompass only a small fraction of the complete translation relation that must be learned.

Compared to the methods described in the section 'Rule-based Approaches: Towards More Abstraction' above, corpus-based methods can be broadly characterized as more robust but less precise. This characterization occurs because they tend to have simpler internal structure and because by definition they do well on frequent phenomena. In general, the result is that corpus-based systems exhibit less variation in performance across different source sentences. However, an important qualification to this often-cited robustness advantage is that it applies only within the domain of the training corpus. A system that has been trained on Canadian Hansard text will perform dismally on a corpus of car repair manuals, and vice versa. Such domain specificity is a double-edged sword: it is highly advantageous when training corpora are available for a domain of interest, often making it possible to develop an effective system with less effort than it would take to adapt a rule-based system; but when training corpora are not available, it can be a major stumbling block.

There are two main strains of corpus-based MT that are discussed in detail in the following sections. The first is example-based MT (EBMT), which uses the corpus as a source of direct translation examples. The second is statistical MT (SMT), which first derives a statistical model from the corpus, and then uses it to translate.

Example-based Machine Translation

The central idea of EBMT is to translate new texts by reusing existing translations. The longer a text segment, the less ambiguous it is and the more likely it is that its translation is directly reusable. Commercially available *translation memory systems* implement a particularly simple form of EBMT as an aid for human translators. They memorize all source/target pairs of previously translated sentences and when a (quasi) identical sentence appears in a new source text, they automatically retrieve its previous translation. But accidental sentence repetition is not so common. Therefore, translation memories are mostly helpful for texts in which there are reasons to expect sentence repetition (e.g., a new version of a previously translated document).

Since real EBMT systems try to provide translations for all sentences, their matching procedure needs to back off to progressively smaller segments (ultimately, the word or morpheme level) until a match is found. Meeting this requirement means that they must be able: (a) to align the translation examples at a subsentential level so as to extract the translation of the matched segments; and (b) to recombine the segments found in different sentences into a coherent translation.

A simple example will help convey the flavor of EBMT and of some of the problems it faces. Suppose

our system is asked to translate sentence (25), and that its database of previous translations contains the three sentences of (26):

(25) Don't leave before he sees you.

(26a) Don't leave now. → Ne pars pas maintenant.
(26b) Eat before Max arrives. → Mangez avant que Max n'arrive.
(26c) He sees you every week. → Il te voit à chaque semaine.

If the system can align: (a) *Don't leave* with *Ne pars pas*; (b) *before* with *avant que*; and (c) *He sees you* with *Il te voit*, then it can easily recombine these French segments into a mildly incorrect translation:

(27) Ne pars pas avant que Il te voit.

The remaining problems are: (a) the word *Il* should not be capitalized; (b) *que* and *il* should be fused into *qu'il*; and (c) the conjunction *avant que* calls for the subjunctive form of the verb, namely *voie*. These problems result from 'boundary friction' that shows up when assembling together fragments extracted from different contexts. Thus, the EBMT method suggested in the above example needs to be considerably refined.

There is considerable diversity among EBMT approaches, and the subsections below try to give an idea of the main trends.

Abstraction level EBMT approaches replace hand-crafted translation rules with correspondences that are automatically derived from a corpus of translation examples. The issue of the right abstraction level for such correspondences arises in the same way as in rule-based systems. Some EBMT systems, including the first EBMT proposal (Nagao, 1984) use a direct approach: the examples are stored as word strings and the source sentence is directly matched against their source side. But many other EBMT systems are more like transfer-based systems in that they perform the matching at the level of abstract syntactic structures. For example, Watanabe *et al.* (2003) store their examples as pairs of syntactic dependency trees whose nodes are explicitly aligned; sentences to be translated are then parsed and the corresponding dependency tree is matched against the source side of the examples. Intermediate approaches are sometimes used in which part-of-speech tagging and/or named-entity recognition is used as a substitute for full-fledged parsing.

Example Matching Since most input sentences will not be found as such in the example database, a procedure must be defined for decomposing them into smaller elements for which matches can be found. The nature of this procedure is closely related with the previous question of what representations are used. In the direct approach, one can try to match the various substrings of the input with those of the examples; in syntax-based approaches, one will rather match syntactic units.

Since there may be several different ways to decompose an input sentence in terms of partial database matches, some metrics must be used to select the preferred way. One interesting feature of many EBMT approaches is the use of a criterion of lexical similarity. For example, suppose the database contains the following two examples:

(28) Max broke his glass. → Max a cassé son verre.

(29) John broke his promise. → Max a rompu sa promesse.

Given the input sentence *Steve broke his vow*, a typical EBMT system would try to assess which one of *glass* and *promise* is closer to *vow*. Since *promise* is much closer, the system would choose (29) as the best translation model. Similarity is typically defined as the inverse of the distance in the word graph underlying a thesaurus (Nagao, 1984).

Translation Retrieval Once a set of examples has been chosen that covers all the segments of the input sentence well enough, the translation of each matched segment must be extracted from the examples. In order to do that, it is necessary to align the source and target material in the matching and/or nonmatching parts of the examples. To take a simplistic example, suppose the database contains example (30) and we have input sentence (31).

(30) John likes to read novels. → John aime lire des romans.

(31) Mary likes to read poetry.

The unmatched portions of the example are *John* and *novels*. If we manage to align these unmatched parts with their respective TL counterparts *John* and *des romans*, we can then extract the correspondence *X likes to read Y* → *X′ aime lire Y′*. It is not necessarily required to explicitly align *likes* with *aime* and *to read* with *lire*.

Various alignment methods are used by EBMT practitioners, ranging from dictionary-based heuristics to statistical methods comparable to those of SMT (see the subsection 'Statistical Machine Translation' below).

Offline Processing The example database can be processed offline in order to facilitate example matching and translation retrieval.

When highly abstract representations are used, the examples are most often parsed and aligned offline for efficiency reasons. But in some approaches, translation templates are also extracted in advance from the database to be applied at runtime on input sentences. Suppose now that the database contains both (30) above and (32):

(32) Susan likes to read newspapers. → Susan aime lire les journaux.

Then clearly the same logic as above can be used to extract off-line the equivalence *X likes to read Y* → *X′ aime lire Y′*.

When pushed to its extreme, this offline approach can be more or less equivalent to a transfer-based approach in which the transfer rules are produced by machine learning techniques rather than handcrafted.

Statistical Machine Translation

Statistical techniques have been considered for MT since the field's inception, motivated by early successes in cryptography (Weaver, 1955). However, modern SMT began with the work of a group at IBM in the late 1980s, described chiefly in 'The mathematics of machine translation: parameter estimation' (Brown *et al.*, 1993). This seminal article sets out a series of statistical models that have become known as the *IBM models*. These models continue to play a central role in SMT and have found many applications in other areas such as cross-language information retrieval and text summarization. The following subsections begin by looking at statistical methods with an overview of the classical IBM approach, then discuss the *phrase-based* methods that are the current state of the art, and finally touch on some future directions for the field.

The Classical IBM Approach SMT systems work by trying to find the most probable target sentence for a given source sentence (texts are typically translated sentence by sentence). Conceptually, meeting this requirement means enumerating all possible word sequences t in the TL, computing the probability $p(t|s)$ that each will be the *best* translation of the current source sentence s, and in the end generating the t that was assigned highest probability. Two problems need to be solved in order to do this: creating a *model* to give an estimate of $p(t|s)$ for an arbitrary pair of source and target sentences; and designing an effective *search procedure* to find the best target sentence according to the model.

Realistic search procedures must exploit the structure of the model in order to avoid having to test *all* possible target sentences, which is impractical. For example, the sentence-matching model outlined above lends itself to a particularly efficient search algorithm: if the source sentence is found in the corpus, output its most frequent translation; otherwise, output nothing. Effective search procedures for the IBM models are considerably more complex than this and have been an active topic of research since the models first appeared. Because these procedures are similar to those used for phrase-based models, their description is deferred to the next section.

The Source-channel Model As mentioned above, the role of the model in SMT is to estimate the probability $p(t|s)$ for any source sentence s and target sentence t. The IBM models take a *source-channel* (or *noisy-channel*) approach to modeling this distribution. In this approach, which arose in cryptography, the source text is viewed as an encoded version of an original target text, and translation as the process of *decoding* it to retrieve the original text. Decoding is performed with the aid of *two* models: $p(s|t)$, which models the *encoding* process; and $p(t)$, which models the original text prior to encoding. In SMT, these models are known as the *translation model* and the *language model* respectively. The main advantage of using two models instead of just one for $p(t|s)$ is modularity: the translation model can concentrate on the relation between s and t, and the language model on the structure of t, thus simplifying the design of $p(s|t)$ compared to a single model for $p(t|s)$. Also, a separate language model can be trained on unilingual target-language corpora, which are more abundant than parallel corpora.

In technical terms, the source-channel model corresponds to a Bayesian expansion of $p(t|s)$ into $p(s|t)\ p(t)/p(s)$. This leads to the following strategy for translation, which Brown *et al.* (1993) refer to as the *fundamental equation of statistical MT*:

$$t^* = \text{argmax}_t\ p(s|t)\ p(t) \qquad (1)$$

Here t^* is the output translation, and the *argmax* operation represents the search procedure.

The IBM translation models are described below. The language model used in the IBM work and almost all subsequent work is the trigram, originally developed for speech recognition (Jelinek *et al.*, 1992). This model calculates sentence probability as a product of word probabilities, and the probability of each word as essentially the proportion of times it was observed to follow the two preceding words in the training corpus.

Alignments The IBM translation models for $p(s|t)$ are built around the key concept of *alignments*

Figure 7 Alternative IBM-style word alignments for the same sentence pair, assuming French is the SL. Each French word must be accounted for with a single, possibly empty, connection; English words can have any number of connections.

(Figure 7), which are explicit connections between words in the source and target sentences. (Note that these are *word* alignments, not to be confused with the sentence alignments described earlier.) Alignments determine the probability that a model assigns to a source sentence given a target sentence, in ways that vary among the individual IBM models. For computational reasons, alignments are asymmetric: source words can have at most one connection, but target words can have any number.

Because an alignment is not an observable feature of a pair of source and target sentences, the models must assume that any alignment might have occurred, and calculate $p(s|t)$ by summing over the probabilities of all of them. (This is the same as calculating the probability of getting 3 heads in 10 coin flips by summing over the probabilities of all ways in which exactly 3 heads can occur.) In technical terms, alignments are called *hidden variables*, and they are incorporated into the overall translation probability like this:

$$p(s|t) = \sum_a p(s,a|t), \qquad (2)$$

where a is a complete alignment for s.

Parameter Estimation The fact that alignments are 'hidden' poses a problem for estimating model parameters, such as $p(arbre|tree)$, that depend on them. If alignments were explicit, we could estimate such probabilities just by counting the number of times *tree* was connected to *arbre* in the training corpus and dividing by the total number of connections to *tree*. But in the absence of observable links, how can the required probabilities be estimated?

The IBM models solve this problem with the *Expectation Maximization (EM)* algorithm (Dempster *et al.*, 1977), which relies on the trick of replacing actual counts of observed events with *expected* counts derived from the model itself. Because we do not know which valid alignment actually occurred for a given sentence pair, we assume that they all did, but weight the counts derived from each by its probability according to the model. For example, if an alignment a in which *arbre* connects to *tree* was assigned $p(a|s,t) = 0.01$, then we would increment the count of the pair *arbre/tree* by 0.01. This process is called the *expectation-step* or *E-step* of the algorithm. Once counts have been derived from all alignments in the training corpus, probabilities are obtained from them in exactly the same way as sketched above for standard counts with observed events; this process is called the *maximization-step* or *M-step*. It can be shown that if the E,M sequence is carried out iteratively, the resulting parameters will converge to values that maximize the probability of the training corpus according to the model. This property is called *maximum likelihood*, and it is a standard and effective strategy for training probabilistic models.

The IBM Models The IBM translation models for $p(s|t)$ form a sequence, numbered from 1 to 5 in order of increasing complexity and increasingly accurate modeling of the term $p(s,a|t)$ on the right-hand side of equation (2). The motivation for using a sequence of models is to facilitate training: the earlier models are easier to train, and the sequence is designed so that their parameters can be used to help train the later models. The remainder of this section briefly sketches all five models, omitting most of the technical detail from the original IBM paper.

Model 1 (Figure 7) assumes that word connections are independent of each other and *a priori* equally likely, and that the probability of an aligned source word depends only on the target word it is connected to. To visualize these assumptions, it can be helpful to think of the process for generating s and a from t: first choose a length for s, then randomly choose a connection for each position in s, and finally fill in the source word in each position by picking a translation for the connected target word. It is important to realize that it corresponds only to *one* way that t can give rise to s; to calculate $p(s|t)$, the model must take into account *all possible* ways, by summing over all alignments. This calculation turns out to be a product of individual source-word probabilities, each of which is an average over contributions $p(w_s|w_t)$ from all words w_t in the target sentence. The parameters $p(w_s|w_t)$ form a kind of probabilistic bilingual dictionary and are known collectively as the *t-table*. They are the backbone of all five IBM models.

Model 2 is very similar to model 1, but with the addition of a family of parameters that permit it to distinguish among alignments based on the geometry of their connections. The idea is that alignments having connections between words in more or less the same relative position within s and t (like the leftmost alignment in Figure 7) should be more probable than

Figure 8 The model 1 generative process, assuming French is the SL: step 1 chooses a source length, step 2 chooses a connection for each source word, and step 3 fills in the source words with translations of the connected target words.

Figure 9 The model 3 generative process, assuming French is the SL: step 1 chooses a fertility for each target word, step 2 fills in the source words with translations of the connected target words, and step 3 chooses a position for each target word. The connections above the English sentence are empty ones.

those with wildly divergent connections (like the rightmost alignment in Figure 7). Model 2 calculates p(s|t) the same way as model 1, except that the contributions from target words are weighted by position parameters, so they take the form $p(w_s|w_t) \times p(i|j,I,J)$, where $p(i|j,I,J)$ is the weight assigned to a connection between target and source words in positions i and j respectively, within sentences of lengths I and J.

The final three models in the IBM sequence are considerably more complex than the first two. Model 3 (Figure 8) is based on the following generative process: first pick a number of connections for each target word according to a *fertility* distribution $p(\phi|t_i)$, where ϕ gives the number of connections; then choose a source word for each connection as usual; and finally pick a position j for each source word according to a *distortion* distribution $p(j|i,I,J)$, where I and J are target and source lengths. As distortion parameters are similar to model 2's alignment parameters, the main new feature of model 3 is fertility, which captures the propensity of target words to translate to differing numbers of source words. For example, one would expect $p(3|potato)$ to be higher than $p(2|potato)$, reflecting the fact that *potato* usually translates into *pomme de terre*. Fertilities have no connection to the actual words selected as translations, so that model 3 would be happier with *pomme pomme pomme/potato* than with *pomme de terre/potato* if $p(pomme|potato)$ were higher than the other translation probabilities involved in this expression. As there is no efficient way to calculate the expression for $p(s|t)$ in model 3, the sum over all alignments in equation (2) is approximated by a sum over a small set of high-probability alignments found heuristically with the aid of model 2.

Model 4 replaces model 3's distortion parameters with more-refined parameters intended to model the positions assigned to the sets of source words generated by each target word. These parameters treat such sets compositionally, by breaking them into individual source/target connections, which depend upon previous ones. Calculations of alignment sums for model 4 are carried out with the assistance of model 3. Model 5 is similar to model 4; it merely corrects a technical deficiency in the latter by ensuring that the final distribution $p(s|t)$ sums to 1 over all source sentences.

Translation Difficulties It is instructive to consider how the IBM models, in conjunction with a trigram language model, can cope with some of the translation difficulties catalogued in the earlier section 'Why Machine Translation Is a Difficult Problem'.

- *Morphology.* The IBM models are innocent of morphology, and have no idea, for instance, that *tree* and *trees* are more closely related than *tree* and *elephant*. The benefit of this lack of understanding is that they can learn the precise behavior of any words that occur frequently enough in the corpus, regardless of relationships hypothesized by a particular linguistic theory. The drawback is that they are completely unable to generalize along this dimension. For example, they are not able to infer that *trees* translates to *arbres* from knowledge that *tree* translates to *arbre*.
- *Idioms and other multiword relations.* The IBM models have no direct mechanism for coping with idioms, since the only explicit relations they capture are word-to-word (i.e., the t-table). Their main indirect mechanism is the fertility concept, which can encourage single target words to connect to multiple source words. Combined with distortion parameters to capture positioning of sets of source words, and the idea of summing over multiple alignments, this connection gives them a capability to model general many-to-many relations, albeit only a very weak one. The language model enhances this capability by enforcing correct ordering and potentially filling in gaps in multiword idioms.
- *Source ambiguities.* Ambiguities requiring extrasentential knowledge to resolve are out of reach for the IBM models, due to their assumption that sentences are independent units. For other types of ambiguities, the main strategy is just to choose the

most frequent translation. This choice by frequency is bolstered to some extent by potential interactions among words, such as when a source sentence containing *light* and *shine* induces a preference for *lumière* over *lèger* as the translation of *light* due to a learned association between *shine* and *lumière*. The fertility parameters and the language model can also play an indirect role in resolving source ambiguities.

- *Grammatical and word-order differences*. Distortion parameters give model 4 a crude notion of word order that essentially relies on the positions of connected source word sets to determine the relative positions of consecutive target words. Even cruder, but with potentially wider scope, model 2's alignment parameters would in theory allow it to capture gross systematic word-order differences such as between an SVO and an OVS language.

Phrase-based Translation The current state of the art in SMT is distinguished from the classical approach of the previous section mainly through the use of *phrase-based* models, which were first introduced by Och and Ney (2004). The description presented here is based on work by Koehn *et al.* (2003), who give a synthesis of Och's method and related approaches by other researchers. After describing phrase-based models, two other key techniques of modern SMT are briefly discussed, namely dynamic-programming search algorithms and minimum-error-rate training.

Koehn's model is described by the generative process shown in Figure 10. First, the source sentence is split into 'phrases,' which are really just n-grams of various lengths. Next, each source phrase is translated into exactly one target phrase. Finally, the target phrases are re-ordered and concatenated to form the output sentence.

This is a much more intuitively appealing process than the ones for the IBM models described in the previous section. The initial step of splitting the source sentence into phrases is a plausible strategy for *human* translation, in which one selects the portions of the source sentence that can be translated as independent units. For example, *look up* should be treated as a phrasal verb and translated as *chercher* in contexts like *look up a word in the dictionary*; but it can be treated compositionally as *look* followed by *up* in other contexts such as *look up into the sky*. Given this definition of splitting, IBM-style fertility parameters are unnecessary, because all phrases translate one-to-one. Furthermore, distortion parameters can be much simpler because they apply only to the reordering of phrases and not to their (fixed) contents.

Each step of the generative process corresponds to a family of parameters in the phrase-based model. By far the most important is the *phrase table*, a collection of phrase pairs (s,t), along with the probability $p(t|s)$ that s will translate into t. This is the phrase-based analog to the t-table in the IBM models. The other two kinds of parameters – ones that govern splitting and distortion – tend to be rudimentary in existing phrase models, and this article will not discuss them further.

Phrase-Pair Induction Unlike the IBM models, Koehn's phrase-based model does not have an intrinsic procedure for parameter estimation; it relies on an externally-specified phrase table. (This reliance is not the case for all phrase-based models – a notable exception is the *joint model* proposed by Marcu and Wong (2002)). The typical way to generate a phrase table is to use the IBM models, first training them on some parallel corpus and then using them to produce word alignments for every sentence pair it contains. The quality of these alignments can be improved by training models in each direction – $p(t|s)$ and $p(s|t)$ – and using heuristics to combine the alignments generated by each. Interestingly, final quality is not very sensitive to the particular IBM model used.

Once an alignment has been established for a sentence pair, the next step is to determine the phrase pairs that are consistent with it. To ensure that extracted pairs are self-contained, only those candidates with no links to words outside the pair are considered valid. Figure 11 shows a sample alignment and the resulting phrase pairs satisfying this criterion.

Figure 10 The generative process for phrase-based models, assuming French is the SL: step 1 splits the source sentence into phrases, step 2 selects a translation for each phrase, and step 3 reorders the translations.

A maximum phrase length is typically imposed to prevent inflating the phrase table with entries that will have very little chance of being used.

After phrase pairs have been extracted from a corpus, probability estimates are made from relative frequencies, i.e., $p(t|s) = count(s,t)/count(s)$. Because different phrase pairs are treated as completely independent *n*-grams, these estimates will generally have the undesirable property of varying widely across related pairs. Different phrase-based variants address this *smoothing* problem in different ways – the most sophisticated is Och and Ney's original *alignment template* approach, which relies on word classes – but none is entirely satisfactory.

Search Recall that the search problem in statistical translation is concerned with finding the most likely translation hypothesis according to the model. The exponential number of possible hypotheses poses a very difficult problem; (Knight, 1999) shows that, for word-replacement models like the IBM series, the problem is *NP-complete*, which roughly means that it is impossible to solve exactly in any reasonable amount of time. Heuristics must therefore be used; fortunately, experimental evidence has shown that heuristics tend to work well for this problem (Germann *et al.*, 2001).

The best current algorithms for phrase-based models are adaptations of *dynamic-programming beam search* techniques widely used in speech recognition. These algorithms maintain a large list of partial translation hypotheses, each of which is a prefix of a complete translation. Hypotheses are extended by choosing some as-yet-untranslated source phrase and appending a translation obtained from the phrase table. When all hypotheses in the list are complete translations of the source sentence, the algorithm outputs the most probable one and stops. Central to this process are two strategies used to keep the size of the hypothesis list from getting too large:

1. Hypotheses that are indistinguishable for the purposes of evaluating possible extensions are merged (the *dynamic-programming* part of the algorithm). Under typical assumptions, this equivalence property holds for any two candidates that have the same last two target words, cover the same set of source words, and whose most recently-translated source phrases end at the same point. After a merge operation, only the hypothesis with the higher probability is retained.
2. Hypotheses that have low probabilities are discarded (this is called a *beam search* strategy, because such hypotheses are considered to fall outside of a beam that illuminates only the best candidates). Unlike the merging strategy, this one is a heuristic, and thus has the potential to cause search errors. To avoid unfairly penalizing longer hypotheses, comparisons are made only among candidates that cover the same number of source words.

Another important component of search algorithms is the mechanism for assigning scores to partial hypotheses. It is crucial that these be as accurate as possible, otherwise good candidates may get pruned away during the beam search. To improve accuracy, the algorithms try to guess the best way to complete each hypothesis, using strategies such as picking the best translation for each untranslated source phrase without regard for word order.

Figure 11 Extracting phrase pairs from alignments. Assuming a maximum permissible phrase length of 4, the valid phrases for the alignment shown are: *i/je*, *i am/je suis*, *am/suis*, *pleased/très heureux*, *present the petition/la présenter*, *the/la*, *the/l'*, *at/à*, *time/instant*. Notice that the phrases extracted are quite robust to alignment errors, which tend to suppress potentially good pairs rather than create bad ones.

Log-linear Models and Minimum Error-rate Training Recall that the source-channel approach combines contributions from a language model $p(t)$ and a 'backward' translation model $p(s|t)$ by multiplying them. This approach has solid theoretical motivations and is highly effective, but it is somewhat inflexible. There may be other sources of information – for example a forward translation model $p(t|s)$ – that we wish to incorporate into the overall probability calculation, but it is not obvious how this might be done.

A well-grounded probabilistic framework for incorporating arbitrary sources of information is the *log-linear* or *maximum entropy* framework, which encodes information sources as *feature functions* $f(s,t)$, and assigns them *weights* according to how valuable they are. The idea of using log-linear combinations instead of the standard source-channel combination is due to Och and Ney (2002), who showed that it could produce significantly more accurate translations, given an appropriate set of features. In

a second influential paper (2003), Och described a *minimum error-rate* strategy for choosing weights so as to directly minimize the errors in a system's output, as measured by a general MT evaluation technique such as BLEU (Papineni, 2001).

An interesting characteristic of Och's minimum error-rate training algorithm is an *n-best rescoring* step, in which relatively small sets of high-probability translation hypotheses are generated explicitly by the search procedure and then reordered by the model. This permits features that would be too expensive to use during the initial search, for instance ones based on global properties of a given source/target sentence pair.

Translation Difficulties It is somewhat difficult to precisely characterize the problems that might be encountered by a phrase-based model coupled with a minimum-error rescoring procedure, because this framework does not place strong limits on the kinds of knowledge that can be encoded as features. Also, unless the length of phrases is restricted, they can in principle handle any phenomena for which there is sufficient evidence in the training corpus. However, their capabilities in this regard will be highly sporadic and will not extend to extra-sentential phenomena like coreference ambiguity and explicitation constraints.

In practice, although the errors committed by phrase-based systems tend to cut across the spectrum of the translation difficulties listed in the previous section, we can make two general observations about their performance. First, because phrases are treated as independent *n*-grams, the model is highly subject to variations in surface form, such as morphology, changes in order, and insertions or deletions. This characteristic can lead to surprising fluctuations in which the system handles a fairly difficult example quite well, but breaks down completely on an apparently trivial variant of it. An even more pronounced effect is that phrase-based output *looks* like it has been translated in small chunks. As Figure 12 shows, it often consists of short segments that are good translations in themselves, but that lack syntactic and semantic coherence with the surrounding context.

Il n'y a pas un groupe ou un organisme qui, à lui seul, ait toutes les ressources et les moyens nécessaires pour y faire face.

It is not just one group or an agency that, at his doorstep, having all resources and well equipped to deal with it.

No single group or agency has the requisite resources to deal with these problems.

Figure 12 Sample output from a vanilla phrase-based SMT system trained on Hansard text, illustrating incoherence among phrase translations. The French source sentence is on top, the output in the middle, and the English reference sentence on the bottom.

Future Directions Due to the successes of phrase-based models, a lot of research effort in SMT is currently aimed at improving them. A major part of this effort has been concerned with attempting to remedy the fragmentary nature of phrase translations through the incorporation of syntax. To date, the most systematic attempt in this vein has been the Johns Hopkins 2003 SMT workshop (Och *et al.*, 2003), in which a minimum-error rescoring approach was used to incorporate various syntactic features. Although many sophisticated techniques were explored, none turned out to give a truly significant improvement over a baseline phrase-based system. The reasons for this failure are not entirely clear, but the limited scope for improvement offered by *n*-best lists may have played a role. Apart from syntax, other work directly aimed at improving phrase-based models includes new methods of extracting phrases – ones that improve on the rather *ad hoc* procedure sketched in the previous section – and new parameterizations for distortion.

Research less directly based on phrase models is also very active. Among other topics, it includes investigations into the use of extra-sentential context, weighted finite state transducers, new grammar formalisms, semi-supervised learning of translation relations, and learning from comparable rather than parallel corpora.

Macro-Jê

E R Ribeiro, Museu Antropológico, Universidade Federal de Goiás, Goiás, Brazil

© 2006 Elsevier Ltd. All rights reserved.

The Macro-Jê stock comprises the Jê family and a number of possibly related language families, all of which are located in Brazil. Macro-Jê is arguably one of the lesser-known language groups of South America, its very existence as a genetic unit being still "a working hypothesis" (Rodrigues, 1999: 165). According to Rodrigues (1986, 1999), whose classification is the most widely accepted among researchers working on Brazilian languages, the 'Macro-Jê hypothesis' comprises 12 different language families: Jê, Kamakã, Maxakalí, Krenák, Purí, Karirí, Yatê, Karajá, Ofayé, Boróro, Guató, and Rikbaktsa. The existence of Jê as a language family has been recognized since early classifications of South American languages (Martius, 1867). 'Jê' is a Portuguese spelling for a Northern Jê collective morpheme ([je] in Apinajé, for instance) that occurs in the names of several Jê-speaking peoples. The term 'Macro-Jê' was coined by Mason (1950), replacing earlier labels, such as 'Tapuya' and 'Tapuya-Jê.'

Comparative Evidence

Recent classifications (Rodrigues, 1986; Greenberg, 1987; Kaufman, 1994) differ as to the precise scope of Macro-Jê, although there is agreement on the inclusion of most of the families (**Table 1**). Except for Karirí (included only by Rodrigues), Greenberg and Kaufman included all the families listed above. In addition, Greenberg included Chiquitano (also included by Kaufman), Jabutí, and Otí. Given the lack of comprehensive comparative studies, the Macro-Jê status of some of these families is still an open question. Although Guató is included in the stock by all of the aforementioned classifications, a case for its inclusion has yet to be made, beyond the superficial, inconclusive evidence presented so far (Rodrigues, 1986, 1999). On the other hand, a preliminary comparison has revealed compelling evidence for the inclusion of the Jabutí family into the Macro-Jê

Table 1 The Macro-Jê Hypothesis[a]

1. **Jê**
   †Jeikó
   Northern Jê: Panará, Suyá, Kayapó, Timbíra (Parkatêjê, Pykobjê, etc.), Apinajé
   Central Jê: Xavánte, Xerénte, †Akroá-Mirim, †Xakriabá
   Southern Jê: Kaingáng, Xokléng, †Ingaín

Machine-Aided Translation: Methods

E Macklovitch, University of Montreal, Montreal, Quebec, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The focus of this article is on machine-aided translation (or MAT), with heavy stress on the word *aided*, and we shall begin by distinguishing MAT from machine translation (or MT) pure and simple. Both, of course, seek to automate the translation process through the use of computers, and in both humans generally have an important role to play. In MT, however, the initiative in the translation process is given over to the machine, and the aim is to automate this process completely, eliminating the human's contribution as far as possible. In MAT, on the other hand, the initiative in the translation process remains with the human translator, and the role of the machine is to assist the translator in performing certain tasks – normally, those that can be automated with a good degree of confidence and reliability. The fact that MT systems often do not succeed in automatically producing a high-quality translation – where high quality is indeed a requirement – and that a human must subsequently intervene to postedit or otherwise improve the machine's raw output should not cause us to lose sight of the fundamental distinction between MT and MAT. Whereas MT ultimately seeks to dispense with the human translator, MAT proceeds from the double recognition that, for high-quality translation at least, the contribution of a human translator is generally indispensable, and furthermore, that this situation is not likely to change for the foreseeable future. Why is this? Quite simply because high-quality translation routinely requires a level of understanding that extends well beyond the literal wording of a source text to encompass unpredictable amounts of real-world knowledge, as well as the capacity to reason over that knowledge. Despite the undeniable progress recently achieved by the new empirical methods in machine translation, such knowledge and reasoning capabilities, remain by and large, beyond the ken of today's computers. Hence, where high quality is a *sine qua non* (and not just information scanning,

or gisting, as it is sometimes called), there will continue to be a need for a human in the translation process, in order to compensate for the machine's limited understanding.

Before we go any further, a brief terminological digression. For the purposes of this article, *machine-aided* or *machine-assisted translation, computer-aided* or *computer-assisted translation* (CAT) are all taken to be synonymous. Another synonymous variant is *machine-aided human translation* (MAHT), which is often contrasted with human-aided machine translation (or HAMT), the latter referring to the manner in which humans are called on to pre-edit source texts or postedit the output of fully automatic MT systems.

A Little History

It is one thing to establish that humans are not about to be evicted from the translation process, at least not for the foreseeable future. But then what exactly will the human's role be in this process? Or, put another way, what is the optimal *division of labor* between man and machine in the translation process?

Yehoshua Bar-Hillel, who was the first full-time MT researcher, was also the first to demonstrate the theoretical infeasibility of fully automatic, high-quality translation – or FAHQT, as he called it – based on his famous "box in the pen" example. (See Bar-Hillel, 1960, particularly Appendix III, *see also* **Machine Translation: Overview; Bar-Hillel, Yehoshua (1915–1975)**.) Regarding the optimal division of labor alluded to earlier, Bar-Hillel felt that it would be best for the human to intervene either before or after the translation operation proper, but not during it. He recognized, however, that this was an entirely empirical question, the answer to which could change as computers became more powerful and our understanding of natural language evolved. In any case, the arguments that Bar-Hillel repeatedly advanced in the late 1950s and early 1960s largely fell on deaf ears. For the great majority of researchers working on the problem of translation automation in those years, FAHQT remained the only goal worth pursuing, and one that they were convinced could provide a practical solution to the growing demand for high-quality translation. Bar-Hillel had no problem with MT as a legitimate research goal; it was the second contention that he found wholly unrealistic. However, it was not until 1966, when the American government published its (in)famous ALPAC report, that MT researchers could finally be convinced that their projects would not help respond to the burgeoning worldwide demand for translation, and then only because government funding for MT research all but dried up (*see also* **Machine Translation: History**).

Insofar as machine-*aided* translation is concerned, it is probably true to say that it did not begin to attract researchers' attention until 1980, when Martin Kay published his seminal paper 'On the proper place of men and machines in language translation.' (*See also* **Kay, Martin (b. 1935)**.) In it, Kay refurbished Bar-Hillel's original argument, to the effect that fully automatic machine translation, although providing an invaluable research matrix within which to study the workings of human language, had very little to offer in the way of practical solutions to the urgent and growing demands being placed on the overtaxed corps of professional translators. The reason, in Kay's view, was quite simple: we cannot successfully automate what we do not fully understand. The designers and developers of fully automatic MT systems were attempting to mechanize an essentially linguistic operation (translation) at a time when the science of linguistics had not yet provided an adequate explanation of how language works.

As a concrete alternative to fully automatic MT – and this was Kay's truly original contribution – he advocated machine-aided human translation, or more precisely, a device he called the translator's amanuensis, now more commonly referred to as a translator's workstation. At the core of his workstation was a sophisticated text editor, complete with a mouse and a split-screen display, one pane being for the source text and the other for the target. (Remember that Kay was advancing this proposal in 1980, before the appearance of personal computers!) Indeed, Kay argued that a well-designed text editor is probably the single most important tool that translators can be provided with; it is certainly the workstation component they will use most intensively. In the next section of his paper, which is entitled 'Translation Aids,' Kay went on to propose a number of ancillary programs specifically designed for professional translators that could be grafted onto this text editor. For example: a shared bilingual lexicon to which users can add various levels of information; a source-text analysis program that flags terms or expressions that occur with higher than normal frequency; and a keyword-in-context program; a document retrieval program that would allow the translator to locate past texts that contain material similar to his/her current text. Many of these suggestions have since been embodied in commercial products, as we will show later. But even more important than the specific details of Kay's amanuensis (at least for our purposes) is the general philosophy of his incremental approach to MAHT. "I want to

advocate a view of the problem in which machines are gradually, almost imperceptibly, allowed to take over certain functions in the overall translation process. First, they will take over functions not essentially related to translation. Then, little by little, they will approach translation itself. The keynote will be modesty. At each stage, we will only do what we know we can do reliably. Little steps for little feet" (Kay, 1980: 226).

Before we begin to catalogue the various types of translation-support tools that have emerged since Kay first advanced his MAHT program, we should mention another historical antecedent, in the form of the large, dedicated terminology banks that first appeared in the early 1970s, such as *Eurodicautom*, which was launched by the European Commission in 1973, and *Termium*, which the Canadian government inaugurated in 1975. In both cases, the goal was to help standardize the technical terminology and official appellations used in large public administrations that were officially bilingual or, in the case of the European Commission, multilingual. In both cases as well, the professional translators in the employ of the EC or the Canadian Translation Bureau were among the first users of these computerized databases, and their particular needs had been carefully considered during the design and development phases. It therefore seems legitimate to consider these term banks as being among the earliest translation support tools.

Since the mid-1970s, both *Eurodicautom* and *Termium* have undergone numerous changes, one of the most important being that they are now accessible to users outside their host organizations. And, of course, many other term banks have since appeared, both in the public and private sectors. Among the characteristics that users most appreciate about these term banks, one is their sheer volume. Both *Eurodicautom* and *Termium*, for example, contain well over a million records, and hence many millions of terms. Another is their reliability, as their records are normally created by bona fide terminologists, following well-defined and rigorous terminological practices. At the same time, this last characteristic represents something of a limitation for working translators, because they are not usually allowed to modify or contribute to the contents of these large, centralized repositories. Moreover, the normalization and standardization of new terminology is a slow, painstaking process and not always carried to a successful conclusion. Hence, in the real world of commercial translation, it often happens that for the same concept, different clients will insist on their own specific terminology. And finally, although these term banks may be enormous, they simply cannot cover all domains with the same degree of detail, particularly in those high-tech domains where progress is now so rapid. Consequently, translators have a need for other kinds of terminological support. They need a means of recording, storing, and retrieving the results of their own terminological research and particular observations; a more flexible tool that would complement rather than rival the large centralized repositories. This is why for many years, even after the appearance of *Eurodicautom* and *Termium*, translators continued to record their terminological observations on file cards, which were sometimes printed up as domain-specific glossaries. It was only with the advent of the personal computer in the early 1980s, that it became possible to envisage automating these manually produced glossaries in ways that would be affordable, while at the same time increasing their utility and efficiency for working translators.

Terminology Management Programs

Finding the correct lexical equivalent to source-language (SL) words is clearly a necessary (though obviously an insufficient) condition for translation. Hence, it is not altogether surprising that terminology management programs, intended to meet the needs mentioned in the previous paragraph, were among the earliest specialized translation aids to appear for the new generation of personal computers. The first such commercial application was probably *Mercury/Termex* (MTX), developed under the direction of Alan Melby of Brigham Young University. MTX was a memory-resident program that ran invisibly in the background until the translator called it to the screen by hitting a hot-key combination from within the word processor. When the MTX pop-up window appeared, the translator would then type in the term to look up, and the program would display the corresponding record, if one was present in its database. Using various hot-key combinations, the translator could also insert a target-language (TL) equivalent directly into a word-processing document and, of course, edit or add new records to the terminology database. Other administrative routines were also available for sharing personal glossaries by importing, exporting, and merging term data files.

There are now a plethora of terminology management programs that offer essentially the same basic functions as MTX, some as stand-alone products, others as components of larger translator workstations (see following). What are the characteristics that translators appreciate most about such programs? One obvious benefit, common to all computer-based lexical resources, is the fact that

they allow for much easier and more flexible look-up than any printed volume or collection of file cards. Translators do not have to get up from their desk to query a term; in fact, they do not even have to remove their hands from the keyboard. Moreover, most term management programs now allow for queries, not just on the headword, but also on the content of other fields. Suppose, for example, that the user cannot remember a certain headword but knows that some other word appears elsewhere in the body of the entry. It is extremely unlikely that she would be able to find the entry in question in a bound dictionary, although this would pose no problem for a term management program that indexed the content of all its fields. And the same applies, *a fortiori*, to systems that permit searches with wildcard characters and variable word order. Moreover, most such systems allow the user to specify multiple search criteria, so that they can retrieve, for example, only those terms that belong to a particular domain, on records that were created after a given date, or by a particular person. In short, these term management programs bring to the domain of terminology many of the benefits of other types of computerized database management systems.

Another major advantage of these systems, which was only fully realized when individual PCs were linked up in a local area network, is the ease with which they allow individual users to share the results of their terminological research. Once their machines are linked, it becomes possible for one user to immediately have access to new or modified records entered in the database by another user. Of course, this raises obvious problems of database management, such as how to ensure the integrity and the coherence of the database; but none of these problems are insurmountable, and users have generally found that the advantages of sharing their terminological resources far outweigh the costs. (We will return to consider other, more advanced features of recent term management programs later.)

Other Lexical Aids

The term management programs described in the previous section are primarily intended for a translator's personal terminology, i.e., as a repository for the equivalents encountered or researched in the course of personal work. In addition to these programs, and to the bona fide term banks such as *Termium* and *Eurodicautom*, other lexical resources also form part of a translator's basic tool kit, most notably standard bilingual dictionaries. Needless to say, these too stand to benefit from the increased power and flexibility that are afforded by electronic databases. Interestingly, one of the first to realize this was Alan Melby, who also designed the first personal term management program. In the 1990s, Melby's company obtained the rights from several well-known publishers to include the contents of certain of their bilingual dictionaries within the MTX product offering. As a result, MTX was able to provide its users with two levels of lexical assistance: when a term was queried that was not in the user's personal glossary, the system would display the corresponding entry for that term in one of its standard bilingual dictionaries, albeit in MTX format. Somewhat surprisingly, it took the publishers of the best-known bilingual dictionaries some years to respond to the PC revolution and to release their own versions of their standard and still invaluable reference works.

Translators also make use of other *monolingual* lexical resources, including dictionaries, spelling checkers, and even verb conjugation programs. Although these are undeniably useful, their usefulness is certainly not limited to translators. This is why we will have little to say about them here, preferring instead to concentrate on those tools that are designed specifically for translators and that support them in the central and inherently bilingual aspect of their work.

In our discussion of the terminology management programs earlier, it was tacitly assumed that it is up to the translator to identify the terms that should be added to the system's database. In the early 1990s, some researchers (notably Justeson and Katz, 1993) proposed some surprisingly simple techniques that would allow for the *automatic* identification of candidate terms in a given text. The techniques involved were part-of-speech tagging (*see* **Part-of-Speech Tagging**), followed by the extraction of those word sequences in the tagged text that correspond to well-established term patterns (e.g., *adjective–noun–noun* in English), and finally the merging and sorting of the results in order of descending frequency. This algorithm was said to work best on long technical texts, and then only for multiword terms; furthermore, the candidate terms always had to be vetted by a human translator or terminologist. Nevertheless, the results obtained, particularly at the top of the list, very often corresponded to legitimate terms and would therefore be of value to translators who wanted to research their terminology before beginning their translation. But again, these early term extraction programs were monolingual and left the job of locating the TL equivalents of the proposed SL terms to the human translator or terminologist.

It was not long, however, before researchers moved to correct this deficiency. In 1994, Ido Dagan and Ken Church published a paper that provided the logical

extension to monolingual term extraction, in the form of a program (called *Termight*) that operated on parallel texts (i.e., texts that are mutual translations) in order to identify candidate terms along with a proposed translation. Actually, Church had been one of the pioneers in the development of automatic alignment algorithms that serve to create large bitextual corpora (i.e., parallel texts in which the translational correspondences are rendered formally explicit). In *Termight*, a word-level alignment program was used to calculate the proposed target language equivalents of the candidate terms, and according to the authors, the system was deployed with success at the AT&T Translation Services, leading to marked productivity increases in bilingual glossary construction.

In recent years, there has been much activity in this area of automated term extraction. Monolingual term extraction programs are now available for a wide range of languages, and there are even some commercial products that, like *Termight*, propose translations for the candidate terms, e.g., *TermFinder* from Xerox (now marketed by Temis) and, more recently, *Term Extract* from Trados.

Repetitions Processing

The basic idea behind repetitions processing in the context of translation is as simple as it is appealing: a translator should never have to retranslate a given SL segment if an acceptable translation has already been provided for that segment. The job of the repetitions processing program is to determine which segments in a new text have already been translated and then to provide the translator with easy access to the previous translations of those repeated segments. This is usually done in the following manner: The repetitions processor first segments a new text to be translated into basic units; these are generally sentences, but may also include headings, list elements, or the contents of each cell in a table. It then takes each source unit in turn and conducts a search for it, as a simple character string, in a reference file (or bitextual database) made up of source and target language translation pairs. If a repetition of a source unit is found, the associated target segment is retrieved from the database and shown to the translator, who may or may not decide to incorporate it into his/her translation. (Alternatively, if the repetitions processor is operating in batch mode, the translation will simply be inserted into the provisional target text, or the source sentence may be flagged in some way so that it need not be retranslated.)

This somewhat simplified description raises a number of important questions. The first concerns the nature of the repeated segments: Are they always full sentences, or other complete textual units like headings or list elements? And the second concerns the nature of the bitextual database in which the processor searches for repetitions: How exactly is it constituted? As it turns out, the two questions are interrelated. The default processing unit in almost all commercial repetitions processing systems – which are commonly called *translation memories* (TM) – is the complete sentence, because this is the unit for which it is easiest to build up large-scale databases of past translations; and the usefulness of this kind of tool is obviously correlated with the size of its databases (*see also* **Translation Memories**). Most such systems operate interactively, as follows: If no match is found for a given sentence in the text being translated, the translator must furnish the target language equivalent for it, as would normally be done. When that translation is completed and the translator moves on to the next sentence in the text, the repetitions processor links and stores the previous source- and target-language pair in its current database, so that if the source sentence is repeated later in the text, the system will be able to retrieve the associated translation. Now, suppose that later in the text, a source sentence is encountered that repeats only part of the SL-TL pair that has just been stored; say, its verb phrase, i.e., the auxiliary, the main verb and the noun phrase that serves as its direct object. The repetitions processor *might* be able to locate the repeated source sequence in its database, although even this is far from obvious. (How does one know which subsentential sequence to search for without searching for them all, thereby opening the door to a combinatorial explosion?) But even if this problem could be resolved, how would the repetitions processor know which subsegment to retrieve from the associated target sentence? Some sort of linguistic analysis would have to be performed in order to determine just what part of that TL sentence corresponds to the translation of the SL verb phrase. Unfortunately, this cannot currently be done with a high degree of precision and reliability. Current automatic alignment technology is quite accurate when it comes to linking corresponding sentences in two texts that are mutual translations; see, e.g., Véronis (2000). However, performance drops substantially when automatic alignment is attempted below the sentence level; see, e.g., the results reported in (Mihalcea and Pederson, 2003). This is another reason why all commercial repetitions processors employ the full sentence as their default processing unit: by so doing, their search and retrieval can be fully automatic. (Notice, incidentally, that there is nothing to prevent subsentential segments from being *manually* identified and stored

alongside their translation in the database; but then the problem is how to scale up.)

Given the current state of repetitions processing technology, a reasonable question to ask, therefore, is the following: How often do complete sentences reappear verbatim in general texts? Needless to say, the question does not admit of a pat answer, in the form of a simple figure that would apply across the board to all types of texts. However, from a study that we conducted on thousands of queries submitted to an online bitextual database containing 70 million words of Canadian parliamentary debates (see Macklovitch, 2000), the answer would seem to be: not very often. More precisely, what we discovered in this study was that as the queries submitted to this database (*TSrali*) lengthened, the likelihood of finding an exact match decreased proportionally; when the queries reached 14 words in length, there were no longer any exact matches or repetitions. (Similar findings are reported by Langlais and Simard, 2002, who found that less than 4% of 1260 complete sentences submitted to a much larger Hansard database were repeated verbatim.) Perhaps we tend to underestimate the degree to which natural language is creative, as Noam Chomsky argued long ago in *Syntactic structures*. Be that as it may, what these findings suggest for repetitions processing is that any system that searches for verbatim repetitions of complete sentences will be of very limited use, except on those types of texts that happen to display a high degree of repetition, such as updates, or certain types of technical manuals in which the same commands may appear over and over again. In terms of the general worldwide demand for translation, however, these surely represent only a small proportion of the texts that need to be translated.

The developers of commercial translation memory software are certainly aware of this problem and in response have attempted to extend the applicability of their systems by introducing a number of features meant to attenuate the definition of what constitutes a repetition of the same sentence. Suppose, for example, that a sentence in the text being translated matches a SL sentence in the database except for the value of a proper name or a certain numerical expression, such as a date or an amount of money. A translator would normally want to see the previous translation for this SL sentence, particularly because the named entities it contains are often left untranslated. Some translation memory systems will in fact treat the two sentences as though they were identical and may even replace the values of the named entities in the previous translation with the appropriate values from the new source sentence. Indeed, most commercial TM systems now incorporate a notion of 'fuzzy matching,' which allows them to accommodate this and other sorts of nonidentical but similar SL sentences, where the degree of similarity is expressed in terms of a numerical coefficient that the user may adjust in order to constrain the search for approximate matches. How exactly do these fuzzy matching algorithms work? It is difficult to say with certainty, because TM vendors do not generally provide a formal definition of this similarity coefficient. Hence, it is not all obvious how the results of a 70% match will differ, say, from a 74% match or an 81% match. One suspects that some notion of edit distance is being employed; but when evaluating two SL strings, the matching algorithm may also take other factors into account, such as whether the translation has been produced by an MT system or by a human, or whether the database contains multiple equivalents for the same SL segment – not to mention the opaque effects of word order differences on the similarity coefficient. Combining such diverse factors into a single percentage may appear to make things simpler for the naïve user; but the unfortunate result is that those same users are left with a vague and ill-defined understanding of a parameter that is central to the system. As (Hutchins, 2003a) remarked: "most TM systems have difficulty with fuzzy matching – either too many irrelevant examples are extracted, or too many potentially useful examples are missed" (p. 11).

Another weakness in many current TM systems, attributable to the structure of the underlying database, is that in these systems, the very notion of a document is lost. When a repetitions processor submits each successive sentence of a source document to the bitextual database, it does so blindly, as it were, without any trace of the context from which it was extracted. Moreover, the contents of the database are also stored as isolated sentences, with no indication of their place in the original document. As every translator knows, however, it is not always possible to translate a sentence in isolation; the same sentence may have to be rendered differently in different documents, or even within the same document, as Bédard (1998) convincingly argues. It is not hard to come up with examples of phenomena that are simply not amenable to translation in isolation; cross-sentence anaphora is one obvious case, but there are many others. Skeptics may argue that such problems are relatively rare, but they are missing the point. In order to evaluate a translation retrieved from memory, translators routinely need to situate that target sentence in its larger context. Current TM systems offer no straightforward way of doing this because, unlike full document archiving systems, they archive isolated sentences.

This may seem to be excessive criticism of current translation memory systems. After all, this technology is in wide use nowadays and is generally appreciated by translators and translation service managers, unlike fully automatic machine translation systems. If we have chosen to focus on some of the shortcomings of current TM systems, rather than extolling their virtues, it is mainly to highlight the fact that their applicability remains limited to a narrow range of texts that happen to exhibit a high degree of repetition: essentially, updated documents and certain types of technical manuals. In all other document types – in the vast majority of translation situations, in other words – the repetition of complete sentences is quite rare. Hence, the usefulness of repetitions processing technology is necessarily limited, at least until such time as these systems acquire the capability of handling repetition below the level of the complete sentence. See Macklovitch and Russell (2000) for further development of this argument.

Another reason for our criticism of current TM systems stems from the quasihegemony they seem to enjoy in the field of machine-aided translation. For many people, the terms *translation memory* and *computer-assisted translation* are virtually synonymous. This is regrettable, in our view, because it tends to obscure the fact that repetitions processing is just one type of translation support tool, albeit a useful one for certain kinds of repetitive documents. Nevertheless, with time, there is no doubt that we will see the emergence of many other types translation support tools, thereby relegating repetitions processors to their proper and modest place. Indeed, as we will show in the next section, there exist other ways of exploiting the very same bitextual databases on which repetitions processors are based.

Other Tools Based on Bitext

> Existing translations contain more solutions to more translation problems than any other existing resource (Isabelle *et al.*, 1993).

This assertion must have appeared quite audacious when it was first published back in 1993; but if one thinks about it for a moment, recalling the hundreds of millions of words that are translated every year, it just has to be true. The real challenge, of course, is how to render all the richness lying dormant in past translations readily and easily available to human users. Repetitions processing is one way of doing this, although it is certainly not the only way. For Pierre Isabelle and his colleagues in the machine-aided translation group at the CITI, the key to this challenge lay in what was then the novel concept of bitext, i.e., pairs of texts in which the translational correspondences have been made formally explicit. In the early 1990s, progress in automatic alignment techniques had made it possible to create enormous bitextual databases that were accurately aligned at the sentence level. The question then was: How could these be exploited to help support human translators?

One rather straightforward way of allowing translators and other users to benefit from databases of past translations is via an interactive bilingual concordancing tool, like the *TransSearch* system first developed at the CITI by Michel Simard (see Simard *et al.*, 1993). From the user's point of view, a concordancer is like a database querying system in which the queries correspond to various sorts of translation problems. Instead of asking colleagues if they've ever encountered a particular problem before and, if so, how they previously translated it, the user submits a query to the concordancer. The system responds by searching for the query in the database and displaying all the occurrences it finds, each in its full sentential context; and because this is a bitextual database, it can also display alongside each result the translation of that sentence in the target language. In that translation lies a potential solution to the original translation problem, which users may decide to recycle, as they see fit.

For our present purposes, it's interesting to note that the bitextual database that is queried via a concordancer like *TransSearch* has exactly the same structure as the databases that underlie commercial repetitions processing systems. (Indeed, some commercial TM packages also include an interactive concordancing facility that accesses the very same databases.) All that distinguishes the two is the manner in which they are queried. One way of expressing this difference is in terms of the trade-off that each effects between automation and flexibility. Repetitions processing provides a higher level of automation, because the system automatically submits each successive sentence in a new text to the bi-textual database, thereby ensuring that no repeated sentences are overlooked. As we have seen, however, this automation comes at the expense of a certain rigidity; because only complete sentences are submitted, repetitions of segments below the sentence level will often be ignored. An interactive concordancer, on the other hand, offers greater flexibility in the units that can be submitted – these may be any arbitrary sequence, from a single word up to a complete sentence, including ellipses – provided the user takes the initiative of manually selecting and submitting the appropriate queries. But regardless of whether the queries are submitted manually (as with a concordancer) or automatically (as with a repetitions processor), the important point to emphasize is that it is the database

itself, that constitutes the true translation memory. For this reason, it seems legitimate to propose a more generic or neutral definition of this term, viz., a computerized archive of past translations that is structured in such a way as to promote translation reuse. Nor is it reasonable to argue that one type of translation memory is *a priori* superior to the other, although each may lend itself better to various configurations of repetition. For texts that exhibit a high degree of full-sentence repetition, a fully automatic repetitions processor will tend to be more suitable; otherwise, an interactive concordancer will likely prove more useful to the translator.

Isabelle *et al*. (1993) contend that the notion of bitext provides the foundation for a whole new generation of translation support tools. One interesting and novel proposal they have made is for a translation checker, which they call *TransCheck*; see Macklovitch (1995) for a more detailed description of the system. As its name suggests, a translation checker is meant to be employed somewhat like a spelling or a grammar checker, to which a user will submit texts in the hope of catching typos or certain flagrant errors of grammar. The errors detected by these tools, however, are all monolingual, whereas in the case of *TransCheck*, the errors the system seeks to flag are bilingual, i.e., errors of correspondence between the source text and a draft translation in a target language. In order to do this, a translation checker must first transform the two texts into a bitext in which the correspondences between segments (generally sentences) are made explicit. Once this is done, the system can then verify those bitextual regions to ensure that they conform to certain well-known properties of an acceptable translation. The properties that are currently amenable to automatic verification tend to be rather simple and straightforward; basically, they involve formal and observable features in the two texts, rather than more abstract semantic properties. So a system like *TransCheck* will scan the generated bitext, one aligned region at a time, and verify that each contains certain obligatory equivalences while exhibiting no prohibited equivalences. An example of the obligatory sort would be the terminological equivalences provided in a client glossary or the correct transcription of various numerical expressions; and an example of the prohibited sort would be false cognates or other types of source language interference. Needless to say, such a system will overlook many veritable translation errors, and it may flag others erroneously; but then so do monolingual grammar and spelling checkers, and this doesn't prevent them from being helpful. In any case, the first commercial products offering rudimentary translation checking capabilities have just begun to appear on the market; e.g., the *ErrorSpy* system marketed by the German firm of D.O.G.

Translator's Workstations

A translator's workstation (TWS), conceived most generally, is a computer-based environment that integrates a number of distinct programs, all of which are intended to assist the human translator in various aspects of work. As we saw earlier, Martin Kay may have been the first to advance the idea of a TWS, which he called the translator's amanuensis. Alan Melby was another influential advocate of this approach; see Melby (1982). A detailed chronicle of the history of the TWS is provided by Hutchins (1998), who highlights some of the lesser-known figures who first proposed various tools that have subsequently become workstation components. The point that we want to emphasize here is that the TWS is indeed an approach, much more than it is a product, and as such it admits of numerous realizations. What all such realizations have in common, of course, is the basic tenet of machine-aided human translation, namely, that it is the human who remains at the center of the translation process. The workstation provides various support tools that are designed to make the translator more productive and ideally to relieve the translator of the more fastidious tasks involved in translation.

A brief word on this notion of integration, which is an essential feature of all TWS. As mentioned, a workstation may comprise disparate applications that were not necessarily intended to function together. Hence, a fundamental requirement of a well-designed workstation is to allow the user to shift focus effortlessly from one component to another and to transfer textual data seamlessly from one application to another. To take one simple example, the user needs to constantly consult his/her terminological glossary while drafting a target text within the word processor and, if the glossary contains the desired TL equivalents, be able to directly insert those terms into the target text with a minimum of keystrokes or mouse clicks. How this is done in practice will, of course, vary from one implementation to another; but in all workstations these kinds of ergonomic considerations are of paramount importance. Today, when almost all personal computers are equipped with operating systems that feature a graphic user interface, the difficulty being referred to here may not be obvious. However, in the first workstation development projects, like the one undertaken at the CITI in the late 1980s, the available interfaces were not nearly as user friendly, and the exchange of data between applications was often a very real problem,

due in large part to hardware memory limitations (see Macklovitch, 1989).

Recall that in the incremental approach that Kay first advocated for his translator's amanuensis, the central component was a specialized text editor; the other dedicated programs were to be gradually grafted onto this editor. Nowadays, more than two decades after Kay's original proposal, there are an impressive number of TWSs available – although not all of them call themselves as such – that offer a variety of translation support tools. Interestingly, almost all of the commercial workstation products are being marketed by the vendors of repetitions processing technology. Hence, it is not altogether surprising that in their promotional literature it is the 'translation memory' that is touted as the central, productivity-enhancing component. In actual fact, all these commercial packages include other programs that render them potentially useful to translators when they are working on texts that do not exhibit a sufficient degree of full-sentence repetition; otherwise, these packages would have limited commercial appeal. Foremost among these programs is terminology management software that allows translators to create, update, and share term glossaries. The more sophisticated commercial workstations may also include automatic alignment programs, term extraction programs that operate on the bitexts that these create from legacy translations, and programs that automatically identify terms in a source text that are found within the term glossary. One significant dividing point among the leading commercial workstations is how they interact with the major word processing packages (read MS-Word). Some TWSs do this by integrating their components directly into Word, via the addition of a toolbar menu, for example. This is said to ease the learning curve for users who are already familiar with Word, while allowing them to access its many useful ancillary features, e.g., monolingual spelling and grammar checking. Trados, which is the current market leader in commercial CAT tools, has adopted this approach, as have some of its smaller competitors, such as LogiTerm. Other workstation packages furnish their own proprietary editors, presumably because this allows them greater autonomy and perhaps better component integration; but they also provide filters to facilitate the importing and exporting of text with the major word processing packages. This is the approach adopted by Atril's Déjà-Vu and by Star group's Transit product.

These commercial workstation packages are now so widespread that one is tempted to say that they dominate the translation landscape. Currently, they all offer more or less the same range of functionalities, most of which have already been touched on in this article. However, at least two other features do deserve to be mentioned, even though (strictly speaking) they may fall outside our scope. The first are source-text analysis programs, which provide statistics on a new text to be translated, most notably the degree of sentence repetition; these statistics are meant to allow for an informed decision on the cost-effectiveness of using repetitions processing on a particular text. The second is direct access to a fully automatic machine translation program. This figured prominently in Melby's original proposal for a multilevel system of translation aids (see Melby, 1982), where full-scale MT was the third, or ultimate, level of automated assistance, just as it was in the historically related ALPS system described in Hutchins (1998). In the 1990s, several major vendors of translation memory technology sought to team up with the developers of commercial MT systems to provide what was vaunted as being the best of both worlds. In these integrated environments, so the argument went, a new input sentence for which no match was found in the translation memory could be sent off for automatic translation by the MT system, after which the translator need only postedit the machine output. (The sequencing of the two processes was significant, the underlying assumption being that past human translations are always preferable to those generated by machine.) There seems to be far less emphasis on such links to full MT systems today. Indeed, of the major CAT system vendors, SDL may be the only one that still offers this option, and even then quite discreetly. One may speculate on the reasons for this important change of strategy. No doubt it had something to do with the quality of the raw translations produced by the large rule-based MT systems that were dominant in the last decade, a level of quality that was probably judged to be insufficient for publication purposes and incompatible with the exacting requirements of professional translators. Indeed, several of those large commercial MT systems have since disappeared or are now targeting very different markets.

Conclusion

In the last few years, there has been much encouraging progress in the general field of translation automation. In terms of core technologies, the new statistical or data-driven methods have now made it possible to develop MT systems with a fraction of the human effort that was formerly required. Moreover, the quality of the translations produced by these corpus-based systems has been steadily improving, to the point that they can now rival that produced by the best rule-based systems. In terms of attitudes as well, there has been significant progress: progress in our

understanding of which types of technology are most suitable for different kinds of translation demands. The general distinction between translation for assimilation purposes versus translation for dissemination or publication purposes is now widely accepted and with it, the recognition that fully automatic MT is often not appropriate for the latter type of translation demand, at least not given the current state of the technology. This is a most welcome development. For too many years, the "all or nothing syndrome," as Alan Melby once called it – "the attitude that the machine must translate every sentence or it is not worth using a machine at all" (Melby, 1982: 215) – resulted in the misdirection of energies and resources among researchers and developers, as well as producing a high level of frustration among users, who felt that automated 'solutions' were being imposed on them that simply did not fit their needs. In the light of this inglorious history, it is altogether refreshing to read the following from someone as informed as John Hutchins: "MT systems are not suitable for use by professional translators, who do not like to have to correct the irritatingly 'naïve' mistakes made by computer programs. They prefer computer aids that are under their full control" (Hutchins, 2003b: 509).

Last but not least, it is also encouraging to see that new types of translation aids are finally being added to commercial workstations, beyond the now standard repetitions processing and glossary management programs. To illustrate with one simple example, several CAT packages now include a program that seeks to detect terms that have been translated inconsistently, i.e., not as the target equivalent specified in the term glossary. Small matter that just such a program was proposed nearly 10 years ago as part of the *TransCheck* system. What's important for working translators and revisers is that this kind of automated assistance, which will help relieve them of a particularly fastidious aspect of their work, is now becoming available. Of course, checking for terminological consistency is but one small element in the overall job of quality assurance in translation. Again, small matter! As Kay so aptly stated so many years ago, in machine-aided translation, it's little steps for little feet. After years of immobility, the good news is that the feet are finally moving, and moving, it would seem, in the right direction.

Machine Translation: Overview

P Isabelle and G Foster, National Research Council of Canada, Gatineau, Quebec, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The term *machine translation* (MT) is used to refer to any process in which a machine performs a translation operation between two ordinary human languages: the *source language* (SL) and the *target language* (TL). This is the sense that appears in the following proposition:

> Machine translation is cheaper than human translation but less reliable.

The term can also designate the product of such a process, as in:

> Reading machine translations is not very pleasant but it is a convenient way to get the gist of foreign-language Web pages.

Finally, machine translation can also refer to the study of methods and techniques that render machines capable of producing (better) translations, as in the title of the present article.

The term applies equally well to written or spoken language, but there is a tendency to prefer the terms *speech translation* or *speech-to-speech translation* for referring specifically to machine translation of spoken language.

Translation is a very effective way of helping people communicate across the linguistic barriers. Unfortunately, human translation is expensive enough that it cannot constitute a practical solution to the everyday needs of ordinary people. As the price of human translation is unlikely to fall substantially, machine translation constitutes our best hope of making translation affordable for all.

The idea of using machines to translate is very old, but it was only around 1950, with the advent of digital computers, that serious work could really start. The initial enthusiasm led many to believe that good-quality machine translation was just around the corner, but they were wrong. After some 50 years of research, we can affirm that, barring an unexpected breakthrough, machines will not be able to compete with human translators in the foreseeable future. This prediction applies not only to difficult material such as literary works, but also to all but the very simplest and repetitive texts (e.g., weather reports).

The present article explains why this is so. We start from a simplistic conception of machine translation and show where it breaks down. Then we show how computational linguists tried to fix the problems through increasingly elaborate approaches. But these more elaborate approaches turn out to raise their own additional problems.

Why Machine Translation Is a Difficult Problem

Let's assume a very naïve theory: translating between human languages is just a matter of looking up the words of the source text in a bilingual dictionary. The next 12 subsections examine the many ways that simplistic theory breaks down and show why translation requires: (a) a fine-grained understanding of the source text; (b) contextual knowledge that makes it possible to fill information gaps between the SL and the TL; and (c) a detailed knowledge of the grammar of the TL.

Segmenting Texts into Words

Before a dictionary search can be performed, the text needs to be segmented into a sequence of individual

Macro-Jê

E R Ribeiro, Museu Antropológico, Universidade Federal de Goiás, Goiás, Brazil

© 2006 Elsevier Ltd. All rights reserved.

The Macro-Jê stock comprises the Jê family and a number of possibly related language families, all of which are located in Brazil. Macro-Jê is arguably one of the lesser-known language groups of South America, its very existence as a genetic unit being still "a working hypothesis" (Rodrigues, 1999: 165). According to Rodrigues (1986, 1999), whose classification is the most widely accepted among researchers working on Brazilian languages, the 'Macro-Jê hypothesis' comprises 12 different language families: Jê, Kamakã, Maxakalí, Krenák, Purí, Karirí, Yatê, Karajá, Ofayé, Boróro, Guató, and Rikbaktsa. The existence of Jê as a language family has been recognized since early classifications of South American languages (Martius, 1867). 'Jê' is a Portuguese spelling for a Northern Jê collective morpheme ([je] in Apinajé, for instance) that occurs in the names of several Jê-speaking peoples. The term 'Macro-Jê' was coined by Mason (1950), replacing earlier labels, such as 'Tapuya' and 'Tapuya-Jê.'

Comparative Evidence

Recent classifications (Rodrigues, 1986; Greenberg, 1987; Kaufman, 1994) differ as to the precise scope of Macro-Jê, although there is agreement on the inclusion of most of the families (Table 1). Except for Karirí (included only by Rodrigues), Greenberg and Kaufman included all the families listed above. In addition, Greenberg included Chiquitano (also included by Kaufman), Jabutí, and Otí. Given the lack of comprehensive comparative studies, the Macro-Jê status of some of these families is still an open question. Although Guató is included in the stock by all of the aforementioned classifications, a case for its inclusion has yet to be made, beyond the superficial, inconclusive evidence presented so far (Rodrigues, 1986, 1999). On the other hand, a preliminary comparison has revealed compelling evidence for the inclusion of the Jabutí family into the Macro-Jê

Table 1 The Macro-Jê Hypothesis[a]

1. **Jê**
   †Jeikó
   Northern Jê: Panará, Suyá, Kayapó, Timbíra (Parkatêjê, Pykobjê, etc.), Apinajé
   Central Jê: Xavánte, Xerénte, †Akroá-Mirim, †Xakriabá
   Southern Jê: Kaingáng, Xokléng, †Ingaín
2. **Kamakã**
   †Kamakã, †Mongoyó, †Menién, †Kotoxó, †Masakará
3. **Maxakalí**
   Maxakalí, †Pataxó, †Kapoxó, †Monoxó, †Makoní, †Malalí
4. **Krenák**
   Krenák (Botocudo, Borúm)
5. **Purí (Coroado)**
   †Coroado, †Purí, †Koropó
6. **Ofayé**
   Ofayé
7. **Rikbaktsá**
   Rikbaktsá
8. **Boróro**
   Boróro, †Umutína, †Otúke
9. **Karajá**

stock (Voort and Ribeiro, 2004), thus corroborating a hypothesis suggested in the 1930s by ethnographer Curt Nimuendaju (Nimuendaju, 2000: 219–221). Greenberg's main piece of evidence for the inclusion of Chiquitano was the entire set of singular personal prefixes (Greenberg, 1987: 44), which are strikingly similar to the ones found in several Macro-Jê families; convincing lexical evidence, however, has not been presented thus far. As for Otí, a poorly documented language once spoken in southern Brazil, the meager available data do not support its inclusion in the Macro-Jê stock.

The only family-level reconstruction available is Davis (1966), for Proto-Jê. So far, lexical comparative evidence supporting the inclusion of individual families in the Macro-Jê stock has been presented for Kamakã (Loukotka, 1932), Maxakalí (Loukotka, 1931, 1939; Davis, 1968), Purí (Loukotka, 1937), Boróro (Guérios, 1939), Krenák (Loukotka, 1955; Seki, 2002), Karajá (Davis, 1968), Ofayé (Gudschinsky, 1971), Rikbaktsá (Boswood, 1973), and Jabutí (Voort and Ribeiro, 2004). In addition, some studies have shown very suggestive cases of morphological idiosyncrasies shared by Jê, Boróro, Maxakalí, Karirí, Karajá, and Ofayé (Rodrigues, 1992, 2000b). Thus, although the inclusion of many of the families into the Macro-Jê stock is being further corroborated by additional research, for others (namely Guató, Chiquitano, and Yatê) the hypothesis has yet to be systematically tested. The precise relationship among the suggested members of the stock also remains to be worked out.

Long-Range Affiliations

Greenberg (1987) suggested that Macro-Jê would be related to his Macro-Pano and Macro-Carib stocks, as part of a Jê-Pano-Carib branch of 'Amerind.' However, as Rodrigues (2000a) pointed out, Greenberg's purported evidence does not withstand careful examination. Rodrigues (1985, 2000a) proposed instead a relationship between Tupí, Carib, and Macro-Jê, noting grammatical and lexical similarities among the three language groups (especially between Carib and Tupí). Davis (1968) also mentioned a few lexical similarities between Proto-Jê and Proto-Tupí. Although the evidence presented so far suggests that Rodrigues's proposal is more plausible than Greenberg's, any hypothesis of distant genetic relationship at such a level must be considered with caution. Considering that the precise boundaries of Macro-Jê are still uncertain, much more research at the family and stock levels needs to be conducted before such long-range classifications can be proposed on solid scientific grounds.

Location

All Macro-Jê languages are spoken in Brazilian territory, although in the past Otúke (Boróro) and Ingaín (Southern Jê), both now extinct, were spoken in Bolivia and Argentina, respectively. Chiquitano, listed as a Macro-Jê language by Greenberg (1987) and Kaufman (1994), is also spoken in Bolivia, as well as in Mato Grosso, Brazil. Although the Jabutí languages and Rikbaktsá are spoken in the southern fringes of the Amazon (Rondônia and northern Mato Grosso, respectively), the overall distribution of Macro-Jê languages is typically non-Amazonian. Yatê, Krenák, and Maxakalí languages are spoken in eastern Brazil, the same having been the case of Purí, Kamakã, and Karirí (all now extinct). Central and Northern Jê tribes, as well as the Boróro and the Ofayé, traditionally occupy the savanna areas of central Brazil. The southernmost Macro-Jê languages are those belonging to the southern branch of the Jê family, spreading from São Paulo to Rio Grande do Sul. Karajá is spoken along the Araguaia River, in central Brazil. The traditional Guató territory is the Paraguay River, near the Bolivian border. Since several purported Macro-Jê languages were spoken in eastern Brazil, a number of them became extinct early on, under the impact of European colonization. Yatê is a remarkable exception, being the only surviving indigenous language in the Brazilian northeast.

Whereas Guató, Rikbaktsá, Karajá, Krenák, and Ofayé are all single-member families (Table 1), the Jê family has a relatively large number of members, for most of which a fair amount of descriptive material is now becoming available (mostly as graduate theses and dissertations in Brazilian universities). Ofayé has around a dozen speakers, although it is mistakenly listed as extinct by some sources (including earlier editions of Ethnologue). Boróro and Maxakalí are the only surviving languages of their respective families. All the languages of the Kamakã, Purí, and Karirí families are now extinct. While documentation on Kamakã and Purí languages consists only of brief wordlists, the Karirí languages Kipeá and Dzubukuá were documented in catechisms (Mamiani, 1698; Bernardo de Nantes, 1709; respectively) and, for Kipeá, a grammar (Mamiani, 1699) – the only published grammar of a non-Tupí language from colonial Brazil. Thus, among the extinct Macro-Jê families, Karirí is the only one for which detailed grammatical information is available. Many of the languages

included in the Macro-Jê stock are seriously endangered (Guató, Ofayé, Krenák, and Arikapú are especially so).

Characteristics

When compared with languages of other lowland South American families (such as Carib and Tupí-Guaraní), Macro-Jê languages typically present larger vowel inventories. For instance, Davis (1966) reconstructed, for Proto-Jê, a system of nine oral and six nasal vowels, as well as 11 consonants. Syllabic patterns are rather simple, obstruent clusters being uncommon. Stress is generally predictable. Phonologically contrastive tone oppositions occur in Yatê and Guató (Palácio, 2004). Processes such as nasal spreading and vowel harmony are generally absent. An exception is Karajá, which presents advanced tongue root vowel harmony, a rare phenomenon among South American languages (Ribeiro, 2002a). Another remarkable feature of Karajá is the existence of systematic differences between male and female speech. Female speech is more conservative, male speech being characterized, in general, by the deletion of a velar stop occurring in the corresponding female speech form (as a result of consonant deletion, vowel assimilation and fusion may also occur). This is a very productive process, applying even to loanwords (Table 2).

Most Macro-Jê languages have a relatively simple morphology. In most languages (including those of the Jabutí, Karirí, Krenák, Jê, Ofayé, and Maxakalí families), productive inflectional morphology is limited to person marking, the same paradigms being generally shared by nouns, verbs, and adpositions alike. Tense and aspect distinctions are generally conveyed by particles and auxiliaries rather than by inflections (with few apparent exceptions, such as Yatê; cf. Costa, 2004). Noun incorporation is rare, having been reported for a few Northern Jê languages, such as Panará (which also presents postposition incorporation; cf. Dourado, 2002).

Table 2 Female versus male speech distinctions in Karajá

Female speech	*Male speech*	
kɔwɔrʊ̃	*ɔwɔrʊ̃*	'wood'
dɪkarã	*dɪarã*	'I'
kɔhã	*ɔhã*	'armadillo'
kədẽra	*ədẽra*	'sand'
ruku	*ru*	'night'
bɛraku	*bero*	'river'
d̪əkɪ	*d̪ɪ*	'3rd person pronoun'
kõbəra	*õbəra*	'to buy' (from Portuguese *comprar*)
kabɛ	*abɛ*	'coffee' (from Portuguese *café*)
bẽkawa	*bẽawa*	'firearm' (from Língua Geral *mokẽãwa*)

In languages with a more robust morphology, such as Karajá, Guató, and Yatê, inflectional morphology tends to be more complex with verbs than with nouns. In Karajá, for example, the verb form includes subject-agreement, voice (transitive, passive, and antipassive), and directional markers ('thither' versus 'hither'), which can be used with evidential purposes (Ribeiro, 2002b); on the other hand, the only category for which nouns inflect is possession (as in most Macro-Jê languages).

The majority of the purported Macro-Jê languages are verb final, with postpositions instead of prepositions and possessor-possessed order in genitive constructions (the exceptions being Guató, Chiquitano, and Karirí). Macro-Jê languages seemingly lack the adjective as an independent part of speech, with adjectival meanings being expressed by nouns or descriptive verbs. Oliveira (2003) offered an in-depth discussion of the properties displayed by 'descriptives' in a particular Macro-Jê language, Apinajé, illustrating well the issues involved in determining part-of-speech membership in languages in which most inflectional properties tend to be shared by nouns, verbs, and adpositions. In attributive constructions, descriptives follow the word they modify.

Languages such as Maxakalí, Karirí, and Panará are described as being predominantly ergative. In addition, a number of Jê languages are described as presenting an ergative split of some sort. That is the case of Xokléng (Urban, 1985) and Northern Jê languages such as Kayapó (Silva and Salanova, 2000) and Apinajé. Among the latter, however, ergativity seems to be rather epiphenomenal, being found only in constructions involving nominalized verbs (such as relative clauses; cf. Oliveira, 2003). Syntactic ergativity is rarely found in Macro-Jê, with the exception of Karirí, in which all grammatical criteria (verb inflection, relativization, switch-reference, word order) point to the absolutive argument (S/O) as being the syntactic pivot (Larsen, 1984).

Further Reading

For information on the main literature on Macro-Jê languages, including an overview of their phonological and grammatical characteristics and a short list of possible Macro-Jê cognate sets, see Rodrigues (1999). Proceedings of recent conferences (the 'Encontros Macro-Jê,' which have been taking place periodically since 2001) help to provide an updated picture of Macro-Jê scholarship; the proceedings of the first

two meetings were published as Santos and Pontes (2002) and D'Angelis (2004), respectively. Population figures for all Macro-Jê groups (including those now monolingual in Portuguese) can be found in Ricardo (2001).

Macrostructure

M M Louwerse and A C Graesser, University of Memphis, Memphis, TN, USA

© 2006 Elsevier Ltd. All rights reserved.

Macrostructures are structures that organize texts globally, just as microstructures organize them locally. Given that texts are not just concatenations of sentences, texts need to be structured both locally (connections between clauses and sentences) and globally (larger fragments of discourse, e.g., paragraphs). Syntactic rules, the meaning of the words of the sentence, and general heuristics of discourse form the microstructure of a text. These microstructures organize sets of interrelated propositional representations of the phrases, clauses, and sentences of the text. Macrorules translate these sequences of propositions into a smaller set of more general propositions by deleting propositions that are less important for the overall meaning of the text, by generalizing propositions into supersets and by constructing new text units that replace the meaning of the old set. Macrorules operate recursively, so that macrostructures that are formed by macrorules may be subject to another cycle of macrorules, further generalizing the gist of the text. Macrostructures are therefore abstract semantic descriptions of the semantic content of the text, similar to the text's global meaning and theme and providing global coherence.

The term 'macrostructure' for global principles of text organization was first proposed by Bierwisch in 1965 for narrative structures in literary texts. In 1968, Harris discussed a similar idea of global text structuring. In that same year the *Morphology of the folktale* by Vladimir Propp was translated from Russian (original 1928). Propp argued that Russian fairy tales share a particular narrative structure. Around that same time, narratologists such as Greimas (1966), Bremond (1964), Labov and Waletzky (1967), Lévi-Strauss (1960), and Todorov (1971) proposed similar narrative grammars. According to these grammars, stories are like sentences in that their narrative structures are structures analogous to syntactic structures. The development of the concept of macrostructures should be seen against the background of the developments of narrative structures.

'Macrostructures' became an established term in text linguistics after being further developed by Van Dijk (1972). Van Dijk's text linguistic approach was very much based on theoretical linguistics and Chomsky's (1957, 1965) generative-transformational grammar. Chomsky (a student of Harris) argued that sentences have a recursive capacity. Each sentence has a deep structure that is interpreted by the semantic component of the grammar. Syntactic transformations relate the deep structure to the surface structure of the sentence. Some of the elementary transformations consist of adjoining, moving, deleting, and copying constituents. Van Dijk argued that text grammars also have these deep and surface structures. The equivalent to the sentential surface structures are microstructures; the equivalent to the sentential deep structures are macrostructures. As with the sentential surface structures, microstructures have underlying rules to represent the underlying semantic representation of the sentences. As with the sentential deep structures, macrostructures have an abstract semantic character and are specified by macrosemantic rules operating on the microstructures. Although the concept of macrostructures remained the same, the direct link to sentence structures faded in later work (Van Dijk, 1977, 1980).

Around the time of Van Dijk's introduction of text grammars in (text) linguistics and poetics, Kintsch (1974) argued that cognitive psychology should not focus on isolated sentences only, but must focus on texts. Kintsch proposed that the representation of texts in memory is a network of interrelated propositions. These propositions are units of meaning roughly corresponding to phrases or clauses. A proposition consists of a predicate that modifies one or more arguments. A sentence like *The teacher explained the concept to the students* can be represented propositionally as (EXPLAIN, TEACHER, CONCEPT, STUDENT). It contains one predicate (EXPLAIN) and three arguments (TEACHER, CONCEPT, STUDENT). Arguments are generally the nouns of a clause, but can also be prepositional phrases and

Macrostructures are structures that organize texts globally, just as microstructures organize them locally. Given that texts are not just concatenations of sentences, texts need to be structured both locally (connections between clauses and sentences) and globally (larger fragments of discourse, e.g., paragraphs). Syntactic rules, the meaning of the words of the sentence, and general heuristics of discourse form the microstructure of a text. These microstructures organize sets of interrelated propositional representations of the phrases, clauses, and sentences of the text. Macrorules translate these sequences of propositions into a smaller set of more general propositions by deleting propositions that are less important for the overall meaning of the text, by generalizing propositions into supersets and by constructing new text units that replace the meaning of the old set. Macrorules operate recursively, so that macrostructures that are formed by macrorules may be subject to another cycle of macrorules, further generalizing the gist of the text. Macrostructures are therefore abstract semantic descriptions of the semantic content of the text, similar to the text's global meaning and theme and providing global coherence.

The term 'macrostructure' for global principles of text organization was first proposed by Bierwisch in 1965 for narrative structures in literary texts. In 1968, Harris discussed a similar idea of global text structuring. In that same year the *Morphology of the folktale* by Vladimir Propp was translated from Russian (original 1928). Propp argued that Russian fairy tales share a particular narrative structure. Around that same time, narratologists such as Greimas (1966), Bremond (1964), Labov and Waletzky (1967), Lévi-Strauss (1960), and Todorov (1971) proposed similar narrative grammars. According to these grammars, stories are like sentences in that their narrative structures are structures analogous to syntactic structures. The development of the concept of macrostructures should be seen against the background of the developments of narrative structures.

'Macrostructures' became an established term in text linguistics after being further developed by Van Dijk (1972). Van Dijk's text linguistic approach was very much based on theoretical linguistics and Chomsky's (1957, 1965) generative-transformational grammar. Chomsky (a student of Harris) argued that sentences have a recursive capacity. Each sentence has a deep structure that is interpreted by the semantic component of the grammar. Syntactic transformations relate the deep structure to the surface structure of the sentence. Some of the elementary transformations consist of adjoining, moving, deleting, and copying constituents. Van Dijk argued that text grammars also have these deep and surface structures. The equivalent to the sentential surface structures are microstructures; the equivalent to the sentential deep structures are macrostructures. As with the sentential surface structures, microstructures have underlying rules to represent the underlying semantic representation of the sentences. As with the sentential deep structures, macrostructures have an abstract semantic character and are specified by macrosemantic rules operating on the microstructures. Although the concept of macrostructures remained the same, the direct link to sentence structures faded in later work (Van Dijk, 1977, 1980).

Around the time of Van Dijk's introduction of text grammars in (text) linguistics and poetics, Kintsch (1974) argued that cognitive psychology should not focus on isolated sentences only, but must focus on texts. Kintsch proposed that the representation of texts in memory is a network of interrelated propositions. These propositions are units of meaning roughly corresponding to phrases or clauses. A proposition consists of a predicate that modifies one or more arguments. A sentence like *The teacher explained the concept to the students* can be represented propositionally as (EXPLAIN, TEACHER, CONCEPT, STUDENT). It contains one predicate (EXPLAIN) and three arguments (TEACHER, CONCEPT, STUDENT). Arguments are generally the nouns of a clause, but can also be prepositional phrases and

even references to other propositions. For instance, the second and third propositions in a text conjoined by the connective *or* can be represented as (OR, 2, 3).

Kintsch's psychological ideas on texts and representations of meaning in memory and Van Dijk's linguistic ideas on text grammars resulted in an impetus in research on discourse comprehension, first resulting in Kintsch and Van Dijk's (1978) influential model of text comprehension. The goal of the model is to explain coherence in text. According to the model, the aim of text comprehension is the formation of micro- and macrostructures. In the comprehension process, meaningful text units are transformed into propositions. Take, for instance, the following extract of a text and its propositional representation:

A number of interesting soccer matches between European teams took place in the early summer days of 2004.
(1) (NUMBER, MATCHES)
(2) (INTERESTING, MATCHES)
(3) (SOCCER, MATCHES)
(4) (BETWEEN, MATCHES, EUROPEAN TEAMS)
(5) (TIME: IN, MATCHES SUMMER)
(6) (EARLY, SUMMER)
(7) (TIME: IN SUMMER, 2004)

Coherence is achieved by an overlap of the arguments in these propositions. The comprehender links the arguments of propositions in order to form a coherence graph. In Figure 1, Proposition 4 is linked to Propositions 1, 2, 3, and 5 by the argument MATCHES. Similarly, Propositions 6 and 7 are linked to 5 by the argument SUMMER. Figure 1 is the representation of the microstructure of the text.

However, there are working memory constraints to linking propositions. According to the model, only a limited number of propositions can stay in one processing cycle. The processing cycle is a temporal period during which propositions are linked. Propositions that stay in multiple processing cycles, and stay longer in working memory, are more memorable. Propositions enter working memory when they are selected by a leading-edge strategy: recent propositions and/or those higher in the hierarchy. Imagine that the processing cycle could hold only four propositions. In this example, according to the leading-edge strategy, Propositions 4, 5, 7, and 3 would move on to the next processing cycle.

Figure 1 Example of coherence graph of text extract.

The macrorules deletion (those propositions whose deletions do not change the meaning of the text are deleted), generalization (sequences of propositions that can be replaced by supersets are generalized), and construction (sequences of propositions that can be replaced by a single proposition are constructed into a single proposition) are carried out on the microstructure to obtain the macrostructure. The above extract is too short to provide a complete analysis, but one can imagine the following macrorules being applied to the microstructure:

Deletion:
(INTERESTING, MATCHES) & (BETWEEN, MATCHES, EUROPEAN TEAMS) → (BETWEEN, MATCHES, EUROPEAN TEAMS)
Generalization:
(TIME: IN SUMMER, 2004) → (IN, 2004)
Construction:
(INTERESTING, MATCHES) & (BETWEEN, MATCHES, EUROPEAN TEAMS) → (PLAY, EUROPEAN TEAMS, SOCCER)

The long-term recall of the text is based on the propositions in the macrostructure of the text. In the above example, a macroproposition like (PLAY, EUROPEAN TEAMS, SOCCER) is a good approximation of the gist of the text, could be used as the title for the text, and is likely to be remembered best.

Microstructures and macrostructures as discussed thus far can be seen as rules and structures of text grammars. Van Dijk and Kintsch (1983) added to these abstract semantic representations of the text the flexibility and fallibility of the user, thereby moving away from the text itself to knowledge–text interaction. One of the problems with the Kintsch and Van Dijk (1978) model and related theories is that text representation is based entirely on the text. The role of the reader's knowledge and the strategies the reader uses in the comprehension process are limited. In addition to a multileveled propositional text base, Van Dijk and Kintsch argue for a situational model that incorporates the reader's interpretations – both correct and incorrect – of the text. The situational model can, for instance, explain individual differences in interpretations of texts, differences in the meaning of translations, and the fallibility and flexibility of memory. It also allows for the text being grounded. In the formation of macrostructures, sociocultural contexts (for instance, cultural

information regarding the situation and the type of interaction) play an important role. In addition to the textual macrostructures, Van Dijk and Kintsch (1983) therefore proposed pragmatic superstructures, schematic structures similar to the rhetorical structure of the text. An example of such a superstructure is a narrative schema or an argumentative schema. Knowing the superstructure of a text allows the reader to anticipate the global organization (macrostructure) of the text.

Kintsch's construction–integration model (1988, 1998) continued and extended the Kintsch and Van Dijk (1978) and Van Dijk and Kintsch (1983) process model. In the construction–integration model, the process from text to mental representation consists of two phases. In the construction phase, an approximate mental model is locally constructed based on the text and the reader's background knowledge. In the integration phase, this tentative mental model stabilizes by filtering out irrelevant and redundant information. An activation process spreads around the network of propositions, boosting strong links between propositions and dampening weak links in order to obtain a well-structured mental representation. The representation resulting from the integration process is then stored in the long-term memory. As with the Kintsch and Van Dijk (1978) and Van Dijk and Kintsch (1983) models, the distinction between microstructure and macrostructure is orthogonal to the distinction between text base and situation model. The text yields a text base. The text base is integrated with the background knowledge of the reader and yields the situation model. This means that two global features characterize the mental representation of a text: its macrostructure and the situational and world knowledge.

Various studies have shown that the macrostructure can significantly predict recall and summarization results. Those propositions that end up in the macrostructure are remembered better than propositions in the microstructure (Graesser, 1981; Kintsch and Keenan, 1973; Kintsch *et al.*, 1975; McKoon and Ratcliff, 1980; Meyer, 1975).

Because macrostructures are higher level properties of sequences of propositions, it is hard to identify linguistic manifestations of macropropositions and their macrostructures at the surface level of the text. However, some indicators of macropropositions can be identified. Titles of texts, summaries, and topical sentences, often at the beginning or end of a paragraph, generally indicate macropropositions. Furthermore, given the properties of coherence graphs, clauses that tend to be conjoined by connectives are good candidates for macropropositions, as are sentences that contain demonstratives and pronouns.

Propositional macrostructures cannot be computed automatically from the text. One of the reasons for this is that the macrorules that can be applied to the microstructure remain underspecified. Kintsch (1998, 2002) has, however, shown how macrostructures can be derived from the text computationally using latent semantic analysis. The meaning of a sentence is represented as a vector in a high-dimensional semantic space. Those vectors that relate most to the overall text (and have the highest typicality scores) can be identified as macropropositions.

Madang Languages

A Pawley[†], Australian National University, Canberra, ACT, Australia

© 2006 Elsevier Ltd. All rights reserved.

The Madang group, containing about 100 languages, is the largest well-defined branch of the Trans New Guinea (TNG) family, which dominates the large island of New Guinea (*see* **Trans New Guinea Languages**). The Madang subgroup occupies the central two-thirds of Madang Province in north central Papua New Guinea (see **Figure 1**). In the east the group's immediate neighbors are languages of the Finisterre–Huon branch of TNG. In the high mountain valleys to the south lie the Goroka, Chimbu–Wahgi, and Engan branches and to the west are unrelated languages, members of the Lower Sepik–Ramu family. The most important innovations defining the Madang subgroup are the replacement of the Proto-TNG independent pronouns **na* '1SG,' **ŋga* '2SG,' and **ya* ' 3SG' by Proto-Madang **ya, *na* and **nu,* respectively (Ross, 2000).

The Madang group probably broke up more than 5000 years ago, after diverging from its TNG relatives in the central highlands. This rough estimate of time depth is based chiefly on lexicostatistical agreements between languages belonging to different primary branches within Madang, which are of the order of 5–15%, lower than those between the major branches of Indo-European. The whole of Madang Province has an area smaller than the Netherlands but contains some 150 languages. Most members of the Madang group have between 500 and 2000 speakers and none has more than about 20 000. This extreme linguistic fragmentation reflects both the considerable time depth of the Madang subgroup and fact that until the colonial era political units in New Guinea seldom exceeded a few hundred people.

The first written records of Madang languages were made in the 1870s but to this day most of the languages are documented only by word lists and sketchy grammatical notes (Z'graggen, 1975b gives a history of research and Carrington, 1996 contains a near-exhaustive bibliography). The best-documented languages are probably Amele (Roberts, 1981, 1987, 1991), Kalam (Pawley, 1966, 1987, 1993; Lane, 1991; Pawley *et al*., 2000; Pawley and Bulmer, in press), and Kobon (Davies, 1980, 1981, 1985). There are detailed grammars of several other languages including Anamuxra (a.k.a. Ikundun or Anamgura) (Ingram, in press), Tauya (MacDonald, 1990) and Usan (Reesink, 1987).

Much of the published comparative work on Madang languages is due to John Z'graggen (1971, 1975a, 1975b, 1980a, 1980b, 1980c, 1980d). He posited a 'Madang–Adelbert Range subphylum' of 98 languages which corresponds closely to the Madang group as defined here, except that Kalam and Kobon (wrongly assigned by Z'graggen following Wurm, 1975 to a putative East New Guinea Highlands microphylum) are now included in Madang and Isabi is now excluded (it belongs to the Goroka subgroup of TNG).

Z'graggen also tentatively proposed an internal classification on typological and lexicostatistical grounds. Recent (and largely unpublished) comparative work using more classical subgrouping methods has led to various revisions in the subgrouping (Pawley, 1998; Pawley and Osmond, 1997; Ross, 2000). Five main branches can be distinguished based

The Madang group, containing about 100 languages, is the largest well-defined branch of the Trans New Guinea (TNG) family, which dominates the large island of New Guinea (*see* **Trans New Guinea Languages**). The Madang subgroup occupies the central two-thirds of Madang Province in north central Papua New Guinea (see **Figure 1**). In the east the group's immediate neighbors are languages of the Finisterre–Huon branch of TNG. In the high mountain valleys to the south lie the Goroka, Chimbu–Wahgi, and Engan branches and to the west are unrelated languages, members of the Lower Sepik–Ramu family. The most important innovations defining the Madang subgroup are the replacement of the Proto-TNG independent pronouns **na* '1SG,' **ŋga* '2SG,' and **ya* ' 3SG' by Proto-Madang **ya*, **na* and **nu*, respectively (Ross, 2000).

The Madang group probably broke up more than 5000 years ago, after diverging from its TNG relatives in the central highlands. This rough estimate of time depth is based chiefly on lexicostatistical agreements between languages belonging to different primary branches within Madang, which are of the order of 5–15%, lower than those between the major branches of Indo-European. The whole of Madang Province has an area smaller than the Netherlands but contains some 150 languages. Most members of the Madang group have between 500 and 2000 speakers and none has more than about 20 000. This extreme linguistic fragmentation reflects both the considerable time depth of the Madang subgroup and fact that until the colonial era political units in New Guinea seldom exceeded a few hundred people.

The first written records of Madang languages were made in the 1870s but to this day most of the languages are documented only by word lists and sketchy grammatical notes (Z'graggen, 1975b gives a history of research and Carrington, 1996 contains a near-exhaustive bibliography). The best-documented languages are probably Amele (Roberts, 1981, 1987, 1991), Kalam (Pawley, 1966, 1987, 1993; Lane, 1991; Pawley *et al.*, 2000; Pawley and Bulmer, in press), and Kobon (Davies, 1980, 1981, 1985). There are detailed grammars of several other languages including Anamuxra (a.k.a. Ikundun or Anamgura) (Ingram, in press), Tauya (MacDonald, 1990) and Usan (Reesink, 1987).

Much of the published comparative work on Madang languages is due to John Z'graggen (1971, 1975a, 1975b, 1980a, 1980b, 1980c, 1980d). He posited a 'Madang–Adelbert Range subphylum' of 98 languages which corresponds closely to the Madang group as defined here, except that Kalam and Kobon (wrongly assigned by Z'graggen following Wurm, 1975 to a putative East New Guinea Highlands microphylum) are now included in Madang and Isabi is now excluded (it belongs to the Goroka subgroup of TNG).

Z'graggen also tentatively proposed an internal classification on typological and lexicostatistical grounds. Recent (and largely unpublished) comparative work using more classical subgrouping methods has led to various revisions in the subgrouping (Pawley, 1998; Pawley and Osmond, 1997; Ross, 2000). Five main branches can be distinguished based

Figure 1 Location of major subgroups of the Madang group.

on innovations in the pronouns (Ross, 2000) and other criteria:

- The Rai Coast group, consisting of about 30 languages, extends along the coastal lowlands from around the mouth of the Gogol River eastwards almost to the mouth of the Mot, and in places extends inland as far south as the Ramu River.
- The Croisilles group of some 50 languages subsumes the 'Mabuso' group and most languages of the 'North Adelbert' group proposed by Z'graggen (1975). Croisilles languages occupy the central Madang coast from the Gogol River north almost as far as Bogia, and cover much of the hinterland west and north of Madang town.
- The South Adelbert group contains 14 languages. Twelve are centered in the South Adelbert Range north of the Ramu River. The other two, Gants and Faita, are spoken south of the Ramu in separate pockets in or close to the Bismarck Range.
- Waskia and Korak, spoken on Karkar Island and on the coast just west of this, form another group.
- A fifth group consists of Kalam and Kobon (each a chain of diverse dialects), spoken around the junction of the Bismark and Schrader Ranges where Madang Province meets Western Highlands Province.

Structural Characteristics of Madang Languages

Phonology

A good many Madang languages have syllables of the shape (C)V and (word finally) CVC, five vowels and between 15 and 20 consonants including series of nasals and oral and prenasalized (or voiceless and voiced) obstruents with contrasts at bilabial, apical, and velar (and often palatal) positions. Members of the South Adelbert and Kalam–Kobon groups resemble unrelated languages of the Sepik and Lower Sepik–Ramu families in making heavy use of a high central or mid central vowel which in some contexts is nonphonemic, being epenthetically inserted between consonants (Biggs, 1963; Pawley, 1966; Ingram, forthcoming).

Grammar

The preferred order of constituents in verbal clauses is SOV but OVS often occurs as a marked structure.

Adpositions follow the verb, determiners and possessors follow the noun. Case marking is generally absent or little developed. Most languages organize pronominal affixes to show a nominative–accusative/dative contrast.

Common nouns are an open class but there are several closed classes of nominal roots such as kinship terms and locatives. In Kalam and Kobon, verb roots are a small closed class of about 130 members but in most Madang languages they are more numerous and probably form an open class. Minor word classes include adjectives, adverb roots, and verbal adjuncts (see below). Many Madang languages distinguish singular, dual and plural independent pronouns in three persons. The dual and plural forms are usually distinguished by a suffix.

Morphology is chiefly suffixal. In certain Madang languages, especially in the west, nouns show considerable morphological complexity, including classifying and case-marking suffixes. In others noun morphology is simple but generally kinship nouns take bound possessor pronouns. Sentence-final verbs are typically inflected for tense-aspect-mood and for subject agreement. In some languages transitive verbs also carry a pronominal prefix or proclitic marking object agreement. Dependent verbs in nonfinal clauses are typically marked for relative tense and subject or topic identity with the final verb.

All languages make extensive use of at least one of the following kinds of complex (multiheaded) predicates: (i) in verbal adjunct constructions, a verb, usually carrying a rather general meaning such as 'make,' 'hit,' or 'go,' occurs in partnership with a noninflecting base (the adjunct), which carries more specific meaning; (ii) in serial verb constructions two or more bare verb roots occur in sequence to express a tightly integrated sequence of subevents. Kalam and Kobon allow up to eight or nine verb roots to occur in a single predicate phrase.

In constructions denoting uncontrolled bodily and mental processes (e.g., sweating, sneezing, bleeding, feeling sick) a noun denoting bodily condition is, arguably, the subject. The experiencer is generally marked by an object/dative pronoun and is the direct object.

Long chains of clauses are commonly used to report a sequence of past events that make up a single episode. Generally, little use of is made of conjunctions to show sequential, conditional, and causal relations. Instead, the main verb in each nonfinal clause carries a suffix which indicates (i) whether the event denoted by the medial verb occurs prior to or simultaneous with that of the final verb, and (ii) whether that verb has the same subject or topic as the next clause. Paragraphlike boundaries are frequently marked by head-to-tail linkage, in which the last clause of the previous sentence is repeated, to begin a new episode.

Madsen Aarhus, Jacob (1538–1586)

A Linn, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Jacob Madsen from Århus in Jutland in the West of Denmark is remembered in linguistics for his pioneering study of general phonetic principles, *De literis libri duo* of 1586. However, like several of the great general linguists of the 16th and 17th centuries, such as Bishop John Wilkins in England, his language work was subsidiary to his principal employment and responsibilities. After eight years studying in Germany, Madsen returned to Denmark in 1574 to take up the professorship of Latin at the university in Copenhagen, to which post Greek was added the following year. In 1580 he became professor of theology, and in the last two years of his life he was rector of the university. He had earlier served as university librarian as well. He left a number of philosophical works as well as linguistic works, but much of the linguistic opus is known only from its titles (*Dictionarium Latino-Danicum*, *Observationes Danicæ*, *Grammaticæ Latino-Danicæ*, *Etymologiæ*, *Syntaxis*, *De cognitione lingvæ*) since his papers were destroyed by fire in the university library in 1728. His lexical and grammatical work prefigures that of the flourishing community of scholars of Danish of the following century, which includes Peder Syv and Erik Pontoppidan.

The first of Madsen's *Two books on the letters* is subtitled *De vera literarum doctrina*. As was usual at the time, he did not distinguish between the spoken and written elements of the *litera*. After an exposition of the anatomy of the vocal organs, he worked through the vowels and consonants in Danish and the three classical languages: Latin, Greek, and Hebrew. This first book concludes with a diagram of his phonetic system, showing it to be built on a series of binary oppositions that force him, among other things, to analyze vowels as either 'tongue vowels' or 'lip vowels.' The second book, *De diversæ doctrinæ incommodis*, deals with a series of problems in the orthography and phonology of various modern and classical languages. In discussing the question of diphthongs and triphthongs in Romance languages, Madsen showed himself to have a good knowledge of recent linguistic work and to be a particular admirer of Petrus Ramus.

The importance of *De literis libri duo* in the history of linguistics is that it is the first extant attempt to deal with general, rather than language-specific, phonetics, and it also provides a useful source of information about 16th-century Danish, not least that of Jutland.

Madurese

B Nothofer, Universität Frankfurt, Frankfurt, Germany

© 2006 Elsevier Ltd. All rights reserved.

Madurese is the third most widely spoken regional language of Indonesia (after Javanese and Sundanese) and the fourth most widely spoken language in the Austronesian language family (after Malay/Indonesian, Javanese and Sundanese). There are more than 13 million speakers from the island of Madura, from neighboring islands (Kangean Archipelago, Bawean, and Sapudi Islands), and from the northern parts of East Java that were settled by immigrants from infertile Madura. Java has the largest number of Madurese speakers (more than 6 million). Stevens (1968) distinguished two main dialect groups, Maduran and Kangean. Within the Maduran group there are three subgroups: West Madurese, with Bawean and Bangkalan dialects; Central Madurese, with Pamekasan and Sampang dialects; and East Madurese, with Sumenep and Sapudi dialects. The Sumenep dialect is regarded as standard Madurese. The Madurese dialects of East Java vary according to the origins of the speakers. Madurese is a member of the Western Malayo-Polynesian subfamily, which includes the languages of western Indonesia and the Philippines. Lexicostatistically, Madurese appears to be most closely related to Malay; it is related to a somewhat lesser degree to the major languages of Java, i.e., Sundanese and Javanese (see Dyen, 1965; Nothofer, 1975). So far, however, no satisfactory qualitative evidence has been adduced that may contribute to solving the question of the relationship of Madurese to its neighboring languages. Madurese shares with Javanese, Sundanese, Balinese, and Sasak (spoken on Lombok) the existence of speech levels, which serve to indicate the social relationships of the discourse participants. Meanings, for which there are low and high forms, are mostly connected with human beings and refer above all to body parts, body actions, clothing, and personal belongings. Pronouns also have status forms. It is generally assumed that speech levels represent a Javanese innovation and that this system and its higher forms are borrowed from Javanese.

Madurese Phonology

Consonants

The Madurese consonant repertoire resembles that of other western Indonesian languages. However, Madurese has a contrast between a voiceless, voiced, and aspirated stop series. Stevens (1968) characterized these consonant series as follows: (1) voiceless stop, 'voiceless, tense stops', (2) voiced stop, 'voiced,

Madurese

B Nothofer, Universität Frankfurt, Frankfurt, Germany

© 2006 Elsevier Ltd. All rights reserved.

Madurese is the third most widely spoken regional language of Indonesia (after Javanese and Sundanese) and the fourth most widely spoken language in the Austronesian language family (after Malay/Indonesian, Javanese and Sundanese). There are more than 13 million speakers from the island of Madura, from neighboring islands (Kangean Archipelago, Bawean, and Sapudi Islands), and from the northern parts of East Java that were settled by immigrants from infertile Madura. Java has the largest number of Madurese speakers (more than 6 million). Stevens (1968) distinguished two main dialect groups, Maduran and Kangean. Within the Maduran group there are three subgroups: West Madurese, with Bawean and Bangkalan dialects; Central Madurese, with Pamekasan and Sampang dialects; and East Madurese, with Sumenep and Sapudi dialects. The Sumenep dialect is regarded as standard Madurese. The Madurese dialects of East Java vary according to the origins of the speakers. Madurese is a member of the Western Malayo-Polynesian subfamily, which includes the languages of western Indonesia and the Philippines. Lexicostatistically, Madurese appears to be most closely related to Malay; it is related to a somewhat lesser degree to the major languages of Java, i.e., Sundanese and Javanese (see Dyen, 1965; Nothofer, 1975). So far, however, no satisfactory qualitative evidence has been adduced that may contribute to solving the question of the relationship of Madurese to its neighboring languages. Madurese shares with Javanese, Sundanese, Balinese, and Sasak (spoken on Lombok) the existence of speech levels, which serve to indicate the social relationships of the discourse participants. Meanings, for which there are low and high forms, are mostly connected with human beings and refer above all to body parts, body actions, clothing, and personal belongings. Pronouns also have status forms. It is generally assumed that speech levels represent a Javanese innovation and that this system and its higher forms are borrowed from Javanese.

Madurese Phonology

Consonants

The Madurese consonant repertoire resembles that of other western Indonesian languages. However, Madurese has a contrast between a voiceless, voiced, and aspirated stop series. Stevens (1968) characterized these consonant series as follows: (1) voiceless stop, 'voiceless, tense stops', (2) voiced stop, 'voiced,

Mid		/*ə*/ ([*ɨ*], [*ə*])	
Low		/*a*/ ([*ɒ*], [*a*])	

lax stop', and (3) aspirated stop, 'voiceless stop with indifferent tension followed by strong aspiration'. Clynes (1995) suggested that the aspirated stop should rather be described as 'lax voice' or 'whispery voiced'. Only Madurese and Javanese oral stops exhibit five places of articulation, both sharing a phonemic distinction between dental and retroflex (described by Stevens (1968) as 'alveolar stop with larger area of tongue contact than dentals') consonants. Another unusual feature of Madurese is the existence of phonemic consonant gemination. All consonants with the exception of the glottal stop also occur geminated. The consonants occurring in the inherited lexicon of Madurese are shown in Table 1 (mainly based on Clynes (1995) and Davies (1999a)).

Vowels

Madurese inherited vocabulary has four vowel phonemes, each one having two allophones, which are pairings of high and low vowels (Stevens, 1968; Clynes, 1995; Davies, 1999a). The phoneme /i/ is realized as [*i*] or [*e*], /u/ as [*u*] or [*o*], /ə/ as [*ɨ*] or [ə], and /a/ as [*ɒ*] or [*a*] (see Table 2). In order to account for vowel allophony, Stevens (1968) established the following three categories of Madurese consonants: D_H, voiced and aspirated stops; D_L, voiceless stops, nasals, and intervocalic /s/; and D_N, liquids, glides, /ʔ/, and morpheme-initial and final /s/. The low vowel allophones occur after D_L consonants, in word-initial position, and after immediately preceding low vowels. The high vowel allophones occur following D_H consonants and after immediately preceding high vowels. The D_N consonants do not affect the quality of the vowel. A vowel preceding these consonants determines the quality of the following vowel. If a vowel occurs after a word-initial D_N consonant, this vowel behaves as though it is word-initial.

Madurese vowel harmony results in verb forms with vowels that differ depending on whether they occur in a bare stem or in an active verb in which the initial consonant of the stem is replaced by a homorganic nasal (the prefix *N*- 'active'). Examples are [*məlle*] 'active.buy' vs. [*billi*] 'buy', and [*napaʔ*] 'active.arrive at' vs. [*d̪ɒpɒʔ*] 'arrive at' (Davies, 1999a).

Morphology

The major morphological processes are affixation and reduplication (see Stevens, 1968). The verbal affixes include prefixes such as *a*- ('perform action indicated by root; perform action on oneself; to own, have, or use'), *ta*- ('to do unintentionally'), *pa*- ('causative'), and *ka* ('agentless passive'). The prefix *N*- marks intransitive verbs (with a meaning such as 'agentless action; reflexive action; be like; be in location') and transitive 'active' verbs, whereas 'passive' verbs are marked by *i*-. A verbal circumfix is *ka–an* 'be affected by'. Verbal suffixes are -*a* ('future, conditional, wished for, possible'), -*ag*^{h}*i* ('treat like, use object as instrument, perform action with, perform action for, make the object be'), and -*i* ('plural, causative'). Nominal affixes include *pa*- (which derives action nouns from intransitive verbs), *paN*- ('agent, instrument, result of action'), *pa–an* ('location, agent, instrument'), and -*an* ('result of action, that which is affected by action, location of action').

There are three kinds of reduplication: reduplication of the final syllable, total reduplication, and reduplication of the first syllable. The usual meanings with verbs are 'repetition or frequency of action; no specified object or goal'; with nouns the usual meanings are 'plural; groups of objects; instrument used to perform action'.

Writing System

Madurese used to be written in a script derived from Javanese script (*hanacaraka*) that originated from the Pallava script of southern India. Today, Latin orthography is common.

Madvig, Johann Nicolai (1804–1886)

D Haug, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

Madvig was a Danish classical philologist and politician. After short, but intensive studies of Greek and Latin at the University of Copenhagen, he was appointed *lektor* ('reader') of classical philology there in 1828. After the completion of his doctorate on an antique commentary on Cicero, he was appointed professor of Latin in 1829 and from 1851 he was professor of classical philology, which he remained until his retirement in 1879. He was also an active politician between 1848 and 1874, and served as Minister of Cultural Affairs from 1848 to 1851, during which time he reformed the Danish educational system.

As an editor, Madvig is most well known for his activities as a text editor, especially of Cicero, and as a conjectural critic. But he also published two very successful grammars of Latin and Greek, which were translated into many languages, and throughout his life he was interested in and worked on questions of general linguistics.

Madvig maintained that no language was in itself superior to any other. To his mind, the importance of the classical languages lay in the role they played in a crucial period in the evolution of European culture, not in any intrinsic superiority of Greek or Latin. He was critical of any attempt to view language systems as reflections of the thought and ideas of the peoples who speak them, thus opposing an idea that was influential in speculative grammar as shaped by the German romantics, notably by Wilhelm von Humboldt. Instead, he focused on language as a means for communication, succinctly stating (Madvig, 1971: 157): "Die Sprache heißt der redende, verstanden sein wollende Mensch." This opinion was at odds with the view of language as an independent organism that was predominant for much of the 19th century.

As a classical philologist, he was particularly interested in syntax. He opposed the dominance of etymology in the linguistics of his time and stressed the legitimacy and the importance of a synchronic approach to language. These views brought him in conflict with the neogrammarians as can be seen from Brugmann's rather condescending review of his linguistic articles (*Literarisches Centralblatt,* 1876).

According to Madvig (1971: 86), the origin of language cannot contradict the presence and life of language, its form of existence. Thus, it can be argued that Madvig introduced uniformitarianism in linguistics, a credit that usually is given to Whitney. In general, Madvig's linguistic theories are close to Whitney's, as he discovered to his dismay on the publication of Whitney's *Language and the study of language* (London, 1867). He himself had published his linguistic papers in Danish and they remained virtually unknown until they were published in German in 1875, i.e., after Whitney's book.

Maffei, Angelus Francis Xavier (1844–1899)

M Almeida, Thomas Stephens Konknni Kendr, Goa, India

© 2006 Elsevier Ltd. All rights reserved.

Angelo Maffei was born on November 12, 1844 at Pinzolo in the Rendena valley of the Alps along the border between Italy and Austria. After classical studies at the gymnasium in Trent, he completed his doctorate in philosophy and doctorate in theology from the Gregorian University, Rome. After being ordained a priest he joined the Jesuit order in 1871, and taught philosophy and theology in Tyrol, Albania, and Dalmatia. In 1878 he came to India as one of the nine pioneering Jesuits to the new Mangalore mission. Maffei worked as an educationist and linguist. He died in 1899 in a remote mission station near Mangalore.

Maffei specialized in the Konkani language of Mangalore. In addition to Konkani, he learned English, Kannada, and Tulu, languages also spoken in Mangalore. In the opinion of his companions he had a flare for languages and a fantastic memory. He was learning Sanskrit, and even tried to learn Malayalam and Tamil when he was in Kerala for a short time. In 1882 Maffei published his first Konkani grammar in English. Though he went about it quite scientifically, he was aware that it was somewhat tentative, as he gave corrections and improvements at the end of the book itself. Maffei's second grammar of 1892, however, is far more compact and concise. The grammarian here was more orderly and sure about his presentation.

In 1883 Maffei published two Konkani dictionaries to help his confrères learn Konkani. The English–Konkani dictionary used the Roman alphabet with diacritics of the Lepsius system to write the Konkani words. The Konkani–English dictionary is smaller, and has the lexemes written in Kannada characters, followed by the Romanized version.

In his two grammars and two dictionaries Maffei constantly kept the Konkani learner in mind; they are targeted at the learner who knows English. For this same reason he gave information on idioms, sayings, and proverbs current among Konkani speakers. His *vade mecum* for confessors, published in 1891, contains specialized Konkani vocabulary to help priests using Konkani. Maffei's grammars and dictionaries are used even today by learners of Konkani in Karnataka state.

Magnetoencephalography

A C Papanicolaou, University of Texas – Health Science Center at Houston, Houston, TX, USA
P G Simos, University of Crete, Crete, Greece
S Sarkari, University of Texas – Health Science Center at Houston, Houston, TX, USA

Magnetoencephalography (MEG) is a totally noninvasive imaging method that allows investigation of cortical dynamics in real time, offering significant advantages over functional brain imaging techniques that rely on hemodynamic measures such as positron–emission tomography and functional magnetic resonance imaging (MRI).

MEG involves the measurement of neuromagnetic signals emanating from the brain (for a detailed discussion, see Papanicolaou, 1998). Most of the magnetic activity measurable outside the head originates from the intracellular current flow associated with postsynaptic electrical events in the long apical dendrites of cortical pyramidal ells. Pyramidal neurons comprise nearly 70% of neocortical neurons, and their long dendritic processes are oriented perpendicular to the cortical surface. As electricity flows along the length of the dendrite, it forms an electric dipole: a pair of electric charges or magnetic poles of equal magnitude but opposite polarity, separated by a small distance.

An advantage of MEG over electroencephalography (and event-related potentials) is that the neuromagnetic signal penetrates the skull and tissues without significant distortion. Magnetic signals associated with bioelectrical activity are very weak, and special techniques have to be employed to discriminate them from extraneous magnetic fields (noise). The instrument used to measure the signals is called a neuromagnetometer, equipped with an array of magnetic sensors, each coupled to a special, low-noise amplifier. State-of-the-art systems are equipped with a minimum of 200 magnetic sensors arranged to cover the entire head. The neuromagnetometer is placed over a person's head, and recording takes place inside a magnetically shielded room designed to reduce extraneous magnetic fields.

During the MEG recording session, the phenomenon that exemplifies the function under investigation is repeated several times while the magnetic flux around the head is being sampled at regular intervals (typically every 4 ms for cognitive and language studies). An external stimulus is invariably presented at each instance in order to either induce the phenomenon (in the case of receptive language functions) or to act as a time cue (in the case of expressive language functions). Each segment of recorded activity, beginning a few milliseconds before and extending several hundred milliseconds after each repetition of the stimulus, is stored separately as an MEG epoch. One such epoch is stored for each magnetic sensor.

The data are filtered and averaged to enhance quality and to remove components of the recorded magnetic flux caused by extraneous sources (mechanical and biological artifacts). Averaging involves computing the magnetic flux across several epochs. The averaged magnetic response emerges as a waveform, or a time-series of magnetic flux measurements at each

Figure 1 Left: Averaged event-related magnetic response to the spoken word 'quiet.' Stimulus onset (set at 0 ms) determines the onset of the response, which consists of an early (~50–200 ms) and a late portion (200–800 ms). Right: Surface distribution of magnetic flux in the form of a contour map measured at 500 ms after stimulus onset over the left hemisphere. Solid circles represent the array of magnetic sensors. ERF, event-related field.

Figure 2 Right: Axial MRI slice displaying activity sources computed during a visual word recognition task. Three distinct cortical areas showed transient increases in neurophysiological activity and were successfully modeled by a series of contiguous current dipoles, one every 4 ms (small white circles). Left: Plots of four complementary measures of the underlying activity in each region. The instantaneous strength of regional activity is indexed by two measures: current moment (Q, or estimated magnitude of the electrical current produced every 4 ms by the population of neurons that showed elevated levels of activity in a given region) and global field power (RMS), which is a direct measure of the magnitude of magnetic flux produced by that electrical current. The temporal aspect of activation is also indexed by two measures: onset latency, which corresponds to the earliest time after stimulus onset when magnetic activity was reliably detected in a given region, and duration of activity, indicated by the number of consecutive 4-ms magnetic activity sources localized in that region. Although correlations among Q, RMS, and duration-of-activity measures are high, duration of activity has the highest degree of empirically established concurrent validity (see text for more details) nA-m = nanoAmperes per meter; fT = femtoTesla.

recording site around the surface of a person's head, as shown in Figure 1. The resulting averaged event-related field consists of early components (50–200 ms after stimulus onset), which correspond to activation of the sensory cortex specific to the modality of stimulus (visual or auditory), and late components (200–~800 ms after stimulus onset), which reflect activation of the association cortex or higher functions.

The surface distribution of magnetic flux at various times can be reconstructed, resulting in a contour map like the one shown on the right-hand side of Figure 1. On the basis of the surface flux distribution, the position and strength of the brain source that produced it can be estimated. This final step consists of the application of a mathematical algorithm that considers the intracranial activity sources as equivalent to electrical current dipoles (Papanicolaou, 1998). Once estimates of the coordinates of the underlying electrical source in the MEG coordinate system are made, they are registered on a set of anatomical images of the brain (from MRI) in order to identify the anatomical location of each source.

The procedures involved in reconstructing cortical activity maps based on MEG data are collectively referred to as magnetic source imaging. Activity profiles consist of a spatial (anatomical) and a temporal component, providing information about where in the brain elevated levels of neurophysiological activity take place and when this activity occurs in relation to stimulus onset. Neurophysiological activation in each brain region where magnetic activity sources are found can be described using four complementary measures (see Figure 2).

Empirical evidence demonstrates that brain activation profiles obtained with MEG represent reliable and valid representations of the brain mechanisms responsible for language functions. MEG affords unique insights into the inner workings of these mechanisms in real time, and this information is at least comparable to the data provided by traditional

Figure 3 A coronal and a parasagittal section of a typical normal participant showing left hemisphere dominance for receptive language functions, and the location of Wernicke's area in the left hemisphere. Each white circle represents one of several temporally contiguous brain activity sources that account for the late (>200 ms after stimulus onset) portions of the brain response to words presented auditorily. Dark circles indicate the location of late magnetic activity sources obtained in response to printed words. Note the overlap of the two activation maps associated with word recognition in the vicinity of Wernicke's area (squares). Activity in Broca's area is found mainly during the (silent) reading task (ellipsoid), presumably reflecting articulatory recoding processes.

research methods in neurolinguistics, namely lesion studies, the Wada technique, and electrocortical stimulation mapping. Several studies establish the concurrent validity of MEG activation and data analysis protocols designed to examine the basic outline of the brain circuits responsible for receptive and expressive language functions.

Validity of Brain Activation Profiles

The main features of the cortical maps common to spoken and written word recognition and comprehension are shown in Figure 3. These are, first, the greater degree of activation of the left perisylvian region, attesting to the well-documented left hemisphere dominance for language in the overwhelming majority of neurologically intact individuals, both children and adults (between 90% and 95% across studies). These MEG-derived hemispheric asymmetries in the degree of regional activation are also in excellent agreement with the results of a standard invasive procedure used clinically to determine hemispheric dominance (the Wada test) in large consecutive patient series (Maestu *et al.*, 2002; Papanicolaou *et al.*, 2004). Interestingly, the closest agreement with the Wada technique is noted when measures of duration of neurophysiological activity are used. Measures of the strength of neurophysiological activity in each language-related region show hemispheric asymmetries in the same direction and approximate degree as duration but are not as good predictors of hemispheric dominance as the Wada test is (Papanicolaou *et al.*, 2004).

A second invariable feature of profiles obtained in the context of receptive language tasks is activation of the posterior portion of the superior temporal gyrus, often extending into the banks of the superior temporal sulcus and the supramarginal gyrus. This finding is in agreement with prior knowledge (and independent of functional imaging) regarding the location of Wernicke's area, specialized for high-level analysis of verbal input (Boatman *et al.*, 1995; Binder *et al.*, 2000). Activation of this region is found during both listening and reading tasks. Activation of the middle temporal gyrus and medial temporal lobe structures is observed mainly when verbal stimuli, whether auditory or visual, are meaningful (pronounceable nonwords result in significantly reduced activation of these regions). Direct tests of concurrent validity showed near perfect agreement between MEG-derived maps of language-specific activity within the dominant hemisphere and the results of direct electrocortical stimulation regarding the precise location and extent of receptive and expressive language cortex (Wernicke's and Broca's areas; Castillo *et al.*, 2001; Simos *et al.*, 1999). These results are important in demonstrating that electrical inactivation of cortical regions that reliably show increased levels of activity associated with a particular linguistic function significantly impairs that function. In addition to providing the means for external validation, this approach is generally very promising as an adjunct to any noninvasive functional imaging method but is difficult to implement mainly due to time constraints and safety considerations associated with direct cortical stimulation studies (see for instance Simos, Breier *et al.*, 2002).

Finally, performance of tasks that exemplify expressive language functions (overt or silent reading, picture naming, and word generation or fluency tasks) is invariably associated with activation in posterior prefrontal areas of the dominant hemisphere

(in the vicinity of Broca's area; Billingsley *et al.*, in press; Castillo *et al.*, 2001; Kober *et al.*, 2001; Salmelin *et al.*, 1994). Typically, activity in Wernicke's area is observed within the first 200–500 ms after stimulus onset, followed by activity in Broca's area, which in turn precedes activity in motor cortices.

Spatial Resolution

While the temporal resolution of MEG is by definition adequate for mapping the temporal course of regional activation in real time, the degree of spatial (anatomical) resolution of the technique had to be empirically established. Spatial resolution of MEG is primarily constrained by the signal-to-noise ratio of the recordings, the suitability of the activity-source model used to convert the raw data into functional images, and finally the accuracy of the coregistration of these images onto the participant's MRI of the brain. Under ideal conditions the localization accuracy for dipolar current sources is on the order of 4–5 mm (Kwon *et al.*, 2002). Under realistic conditions, the estimated spatial accuracy of MEG is only slightly worse and therefore adequate for neurolinguistic investigations, as attested by the following facts. First, intraparticipant reproducibility for the anatomical locations of the sources of both early (50–200 ms) and late (200–800 ms) components of the brain magnetic responses originating in primary and association auditory cortices, respectively, is in the millimeter range (Roberts *et al.*, 2000; Simos *et al.*, in press). This figure is well within the spatial resolution limits of invasive brain-mapping procedures, which are considered the gold standard in the field of neurolinguistics (i.e., less than 8 mm in all cases; Lesser *et al.*, 1994; Ojemann and Whitaker, 1978). Second, MEG data agree with prior knowledge regarding the intrinsic organization of primary somatosensory sensory cortex (somatotopy) (Tecchio *et al.*, 1998) motor (Beisteiner *et al.*, 2004) and primary auditory cortex (tonotopy) (Pantev *et al.*, 1995).

Functional Brain Plasticity

Accumulating evidence indicates that the brain, in the presence of lesions, especially those that have an early onset, is capable of a substantial degree and extent of functional reorganization (e.g., Haglund *et al.*, 1994). Until recently, however, hard evidence to support this claim was restricted to data from invasive studies of patients scheduled to undergo brain surgery. Corroborating evidence to support this claim has been obtained noninvasively using MEG, along with other functional imaging methods (Hertz-Pannier *et al.*, 2002), as part of a presurgical evaluation protocol for patients with intractable seizure disorder. The results indicate that the proportion of patients who are not left hemisphere dominant for language is significantly higher in the presence of a seizure disorder with left temporal lobe onset compared with patients who have space-occupying lesions in the left hemisphere, or normal controls (Pataraia *et al.*, 2004). This group of patients demonstrates a partial shift of the location of Wernicke's area within the left (dominant) hemisphere.

Temporal Resolution

As mentioned in previous paragraphs, a unique feature of MEG compared with other noninvasive functional brain imaging techniques is its temporal resolution. Several findings afford remarkable insights into the temporal dynamics of cortical activation associated with the processing of verbal stimuli.

Temporal Dynamics of Hemispheric Asymmetries for Simple Language Functions

The most pronounced and consistent hemispheric asymmetries are noted for the duration of late magnetic activity, a finding that was originally demonstrated for word recognition and semantic categorization tasks (Simos *et al.*, 1998). Smaller yet significant hemispheric asymmetries are also found in the context of simple phonetic discrimination tasks (Papanicolaou *et al.*, 2003; Eulitz *et al.*, 1995; Roberts *et al.*, 2000). Figure 4 summarizes results from two experiments demonstrating the temporal pattern of hemispheric asymmetries for the duration of activity in auditory association cortex (including Wernicke's area).

Reading and Dyslexia

Another area that has been the subject of many MEG studies is reading. While several studies have focused on the components of the brain mechanism that supports reading in fluent adult readers, others have tried to uncover distinct aberrant features of this mechanism in struggling young and older readers. The majority of studies have examined single-word processing, and only recently have investigators begun to look at words in context, as explained in more detail below. Whenever possible, integration of MEG data with the results of direct electrical interference with cortical function and correlations between MEG and individual performance data have been used to determine the nature of the task-specific operation in which a particular activated brain area is involved (Simos *et al.*, 2002).

The general outline of the activation profile specific to reading features initial bilateral activation of

Figure 4 Time plot of hemispheric differences in the duration of neurophysiological activity in the posterior portion of the superior temporal gyrus during a phonetic discrimination task (upper panel) and a word recognition task (lower panel). (Data from Papanicolaou *et al.*, 2003 and Valaki *et al.*, 2004, respectively.)

occipital regions, followed by activity in left lateral and basal occipito–temporal cortices. This activity occurs reliably between 130 and 180 ms after stimulus onset and is stronger for regular printed material (letters, syllables, or words) than for strings of meaningless symbols of the same length (Tarkiainen *et al.*, 1999). Next, activity is noted bilaterally in the vicinity of Wernicke's area and in the middle temporal gyrus. Finally, magnetic activity sources are found near Broca's area in the inferior frontal gyrus (Simos *et al.*, 2001). While evidence regarding the role of inferior frontal cortices in reading is far from conclusive, it suggests that this area is involved in the articulatory recoding of print, i.e., analysis of printed stimuli according to their corresponding articulatory representations (Pugh *et al.*, 2000).

Reading of meaningful items (real words) entails a higher degree of activation of the left middle temporal gyrus, whereas reading meaningless but pronounceable letter strings (e.g., WOTE) is associated with reduced activation in this region and stronger activity in Wernicke's area (Wydell *et al.*, 2003). The critical role of the superior temporal gyrus for phonological decoding is supported by the finding that transient electrical interference with neural function in this region results in severe phonological processing deficits, including an inability to read pseudowords aloud (Simos *et al.*, 2002). In contrast, the ability to read real words aloud was spared in all cases.

MEG studies employing lexical decision tasks provide support for the view that the early stages of silent, rapid word recognition do not necessarily involve phonological processing or articulatory recoding. In this context, cortical activity along the banks of the superior temporal sulcus (extending into the middle temporal gyrus) precedes activity in the superior temporal gyrus and posterior–lateral frontal cortices (see Figure 5).

The studies reviewed above are important for understanding the dynamic performance of the brain circuit responsible for recognizing printed words as unique linguistic entities, a function that invariably involves lexical access. It is generally held that comprehension of word meaning, which involves access to one or more semantic representations associated with that word, takes place automatically. Few studies have studied the spatiotemporal profile of brain activity that is uniquely associated with semantic access. These studies have examined comprehension of printed words presented in syntactic context, usually words that occur at the end of sentences. Results clearly indicate that semantic access regularly takes

Figure 5 A representative participant's spatiotemporal activation profile in the left hemisphere, elicited in response to word targets in a lexical decision task. The timing (onset and duration) of regional neurophysiological activity in each of the five regions is shown in the graph. The onset of stimuli was at 0 ms, and the participant's mean reaction time was 480 ms (both indicated by vertical arrows on the time line). Abbreviations: Occipital, primary visual cortex; STSp, posterior superior temporal sulcus; STSa, cortex along the anterior banks of the superior temporal sulcus; STG, superior temporal gyrus; frontal, prefrontal cortex.

Figure 6 MEG scans from a 9-year-old boy who never experienced difficulty in learning to read (top set of images) and a poor reader (middle set of images) during performance of a printed word recognition task. Note the clear preponderance of activity sources in the vicinity of Wernicke's area in the left hemisphere (Lt) in the proficient child and in homotopic right hemisphere (Rt) in the poor reader. The poor reader also showed pronounced activity bilaterally in inferior prefrontal cortices (in the vicinity of Broca's area). Bottom panel: Activation maps from the same poor reader after successful completion of an 8-week intensive intervention program. Note the dramatic increase in Wernicke's activation associated with significant improvement in phonological decoding and word recognition ability (solid arrow).

place within the first 250 ms after stimulus onset (Helenius *et al.*, 1998; Simos *et al.*, 1997) and is marked by neurophysiological activity along the banks of the left superior temporal sulcus, in agreement with the single-word data presented above.

MEG studies have been particularly useful in the study of development. Given that the technique is much more child-friendly than any other functional brain imaging method, children as young as 5 years can be tested with very low attrition rates. An important conclusion that stems from these studies is that the essential features of the reading-specific activation profile, described in the preceding paragraph, are in place early in the course of normal development (i.e., at least as early as the end of kindergarten; Simos *et al.*, in press). Longitudinal data demonstrate, however, remarkable individual differences, even among children who eventually develop normal reading skills, suggesting that recruitment of brain areas already specialized for linguistic operations (primarily Wernicke's and Broca's areas) occurs naturally as children learn the alphabetic principle. Considerable changes take place during systematic instruction, especially in the speed of engagement of complex visual processing areas believed to play a critical role in graphemic analysis, and in the relative timing of regional activity.

In addition to establishing the normative activation profile associated with reading, distinct brain activation profiles associated with word recognition and phonological decoding have been found in children with severe reading disability. As shown on the upper and middle panels of Figure 6, these profiles consistently differentiated children diagnosed with severe reading disability from children without reading problems. The most consistent features of the individual aberrant profiles were the lack of activation of left temporo–parietal regions (mainly Wernicke's area), coupled with pronounced activation of the homotopic right hemisphere regions (Simos, Papanicolaou *et al.*, 2000; Simos, Breier *et al.*, 2000). Compensatory increase in posterior prefrontal activity is also found bilaterally. This finding supports the belief that following visual

processing of printed stimuli (complex visual processing areas), disabled readers do not use the left temporo–parietal region for phonological processing of the visual symbols but rather ineffectively employ the corresponding right hemisphere region. Increased prefrontal activity presumably reflects reliance on articulatory recoding strategies to support phonological decoding and word recognition.

Longitudinal data further suggest that the aberrant neural circuit that underlies severe reading problems in older children with dyslexia appears to be present during the early stages of reading acquisition – at a much earlier age than previously believed (Simos *et al.*, in press). Unless intensive, explicit instruction in basic reading skills is provided, this aberrant brain organization may not change. Provided with adequate intervention (i.e., intensive instruction targeting deficient component skills), the aberrant outline of the brain circuit for reading can undergo dramatic change (Simos, Fletcher *et al.*, 2002; see **Figure 6**, lower panel).

As a functional brain imaging technique, MEG has a number of highly desirable features particularly valuable in the study of the brain circuits responsible for language functions. These include millisecond temporal resolution, excellent reproducibility, test-retest reliability, and anatomical resolution. Two other properties that are often neglected in state-of-the-art applications of functional brain imaging are standard features in MEG studies. First, MEG-derived brain activation scans are always presented for individuals rather than for groups of participants, circumventing well-known problems with spatial averaging of functional images (see for instance, Fernandez *et al.*, 2003). Secondly, data acquisition and analysis protocols are empirically validated, allowing legitimate interpretation of studies aiming to elucidate neural networks involved in linguistic processing. Although whole-head MEG is a relatively new technique and the number of research centers focusing on neurolinguistic investigations is small, a considerable amount of data has accrued that confirms classical hypotheses regarding the dynamic organization of brain circuits that support language functions.

Geographical Distribution, Dialects, and Speakers

Malagasy is the main language spoken in Madagascar (population approximately 17.5 million according to a 2004 estimate), located off the east coast of Africa. Standard Malagasy, which is based on the Merina dialect spoken in and around Antananarivo, the capital city, is one of the two official languages (along with French) in Madagascar and is used in public contexts and also for education in grade schools and high schools. There are said to be 18 ethnic groups in Madagascar and regional dialects are referred to in association with these groups. Many show phonemic as well as phonetic, lexical, and morphosyntactic features that are different from those in Standard Malagasy. Descriptions are available for some of the dialects (Tsimilaza, 1981; Thomas-Fattier, 1982; Manoro, 1983; Rabenilaina, 1983; Raharinjanahary, 1984; Beaujard, 1998); however, there are a number of others that have not yet been well studied. The Malagasy dialects are considered to form two groups, a western group and an eastern group (Dez, 1963; Gueunier, 1988), distinguished by two sets of regular sound correspondences, Western Malagasy *di* corresponds to Eastern Malagasy *li*, while Western Malagasy *tsi* corresponds to Eastern Malagasy *ti*. Figure 1 shows the boundary of the two dialect groups, as well as some regional dialect names.

Genetic Relationships

Malagasy is an Austronesian language. Its most closely related language is considered to be Ma'anyan, a language that belongs to the Barito group of the Western Malayo-Polynesian languages. This implies that the people ancestral to the present Malagasy population migrated from southeast Kalimantan on Borneo Island, where the Barito languages are spoken. This took place probably around 700 A.D., but the exact routes and the reasons for this migration are still not clear (Adelaar, 1989; Dahl, 1991). Some Austronesian features in Malagasy reflect borrowings from genetically related languages, in particular Malay and Javanese, suggesting the possibility of multiple migrations after the initial Austronesian settlement in Madagascar, and/or of continuous contact among the speakers. The language also shows traces of contact with the speakers of such languages as Arabic, Bantu languages (in particular Swahili), and Sanskrit.

Writing Systems

The first writing system introduced to Madagascar was an Arabic script. It was introduced by Muslims in the 12th century, and the people in Taimoro learned it and adapted it to their own phonology (referred to as *sorabe* 'great writing/drawing'). Currently, a Latin-based alphabetic system is used, which was introduced in 1823 by an early missionary of the London Missionary Society, David Jones.

Linguistic Features of Standard Malagasy

Phonology and Orthography

The letters used in the Malagasy languages and their phonemic properties are shown in Table 1. In Spoken Malagasy, /h/ often disappears, and word-

The phonetic property is indicated in square brackets, when it is different from the IPA orthography.

final vowels (sometimes even word-final syllables) become voiceless, or are completely lost.

One of the phonological characteristics of Malagasy is the alternation between spirants and their corresponding stops. This is commonly observed in certain word derivations (such as reduplication and some verb derivations, shown in [1]). Alternation also occurs in compounds when a word starting with a spirant consonant follows the consonant *-n*, such as a genitive marker (2b–2d). It also occurs with transitive verbs when an object is incorporated (2a, 2e). (The symbol ` in examples indicates stress.)

(2a) *miàmbina* 'to guard (from)' + *fòdy* 'kind of bird' > *miambim-**p**òdy* 'to guard from birds'

(2b) *òrona* 'nose' + *sàka* 'cat' > *oron-**ts**àka* 'the nose of a cat'

(2c) *tràno* 'house' + *hàzo* 'wood' > *tranon-**k**àzo* 'woodshed'

(2d) *tràno* 'house' + *vàrotra* 'commerce' > *tranom-**b**àrotra* 'business association'

(2e) *lèna* 'wet (with)' + *rano* 'water' > *len-**dr**àno* 'wet with water'

Morphosyntactic Characteristics

Typologically, Malagasy is considered to be a 'pro-drop', verb-initial language that shows the major properties of head-initial languages, with modifiers following the noun and nominal arguments following the verb.

Verbs undergo various morphological derivations that are associated with different sentence structures, as shown here with verbs deriving from the root *pasaka*. In (3), the form *mipasaka* 'to burst open' (the initial consonant appearing as *n* marking the past tense in the example) appears as an intransitive verb requiring only a nominative argument.

(3) **N-ipasaka** ny ovy
PAST-*burst.open* DET *potato*
'the potatoes burst open'

In (4), with the form *manapasaka* 'to smash' (often labeled as 'active voice'), the actor is expressed with a nominative pronoun *aho* 'I,' while in (5) and (6), where the verb forms are *mopasahana* 'to smash something' and *voapasaka* 'have smashed something' (often labeled as 'passive voice'), it is expressed with a genitive pronoun *-ko* 'I (agent).'

(4) **N-anapasaka** ny ovy aho
PAST-*smash* DET *potato* *I*
'I was smashing the potatoes'

(5) **N-opasahi**-ko ny ovy
PAST-*smash-1*SG.GEN DET *potato*
'I smashed the potatoes'

(6) **Voa-pasa**-ko ny ovy
PERF-*smash-1*SG. GEN DET *potato*
'I have finished smashing the potatoes / I have inadvertently smashed the potatoes.'

The form *manapasahana* 'smash with' (often labeled as 'circumstantial') in (7) typically appears in a relative clause modifying a noun which functions as an instrument or a location.

(7) T-amin′ ny sotro no
PAST-*with* *spoon* *that*
n-anapasaha-ko ny ovy
PAST-APPLI.*smash*-1SG.GEN DET *potato*
'it was a spoon with which she was smashing the potatoes'

The alternations observed in Malagasy verb morphology, as well as the various sentence structures in which they occur, are of interest in that they correspond both typologically and historically to the 'focus' system in Philippine and Indonesian languages.

Malawi: Language Situation

S Mchombo, University of California, Berkeley, Berkeley, California, USA

© 2006 Elsevier Ltd. All rights reserved.

Lying south of Tanzania in the Great Rift Valley, wedged between Mozambique to the east and south and Zambia to the west, is the small country of Malawi. It has a landmass of 118 484 square kilometers. Of that, an area of 24 000 square kilometers is taken by a lake that dominates the country's landscape. The lake was previously known as Lake Nyasa, from which the country obtained its former name of Nyasaland. It is the third largest lake in Africa, after Victoria Nyanza (Lake Victoria) and Lake Tanganyika. Although with the change of name of the country from Nyasaland to Malawi the lake was accordingly designated Lake Malawi, political disputes relating to the proper boundaries between Malawi and its neighbors that raged in the late 1960s, led to a reluctance on the part of the government of Tanzania to acquiesce to such a designation of the lake. This renaming was viewed as tantamount to legitimizing the Malawi government's claim, under the leadership, and at the instigation, of its first president, the late Hastings Kamuzu

Lying south of Tanzania in the Great Rift Valley, wedged between Mozambique to the east and south and Zambia to the west, is the small country of Malawi. It has a landmass of 118 484 square kilometers. Of that, an area of 24 000 square kilometers is taken by a lake that dominates the country's landscape. The lake was previously known as Lake Nyasa, from which the country obtained its former name of Nyasaland. It is the third largest lake in Africa, after Victoria Nyanza (Lake Victoria) and Lake Tanganyika. Although with the change of name of the country from Nyasaland to Malawi the lake was accordingly designated Lake Malawi, political disputes relating to the proper boundaries between Malawi and its neighbors that raged in the late 1960s, led to a reluctance on the part of the government of Tanzania to acquiesce to such a designation of the lake. This renaming was viewed as tantamount to legitimizing the Malawi government's claim, under the leadership, and at the instigation, of its first president, the late Hastings Kamuzu

Banda, that the lake as a whole belonged to Malawi. Tanzania claimed, with some justification, that part of the northern extremity of the lake was Tanzanian waters, as the boundary, as originally drawn, included a portion of the lake in Tanzanian territory. This led to the retention of the two labels for the lake, as Lake Nyasa/Lake Malawi, in some of the maps, especially where the publishers expected the maps to be sold in both countries. With altered and somewhat improved political relations between the countries, the label Lake Malawi has become established and accepted, at least provisionally.

Malawi, according to recent estimates, has a population of between 11 and 12 million. It is, by all accounts, a relatively densely populated country. The population of Malawi reflects a diversity of ethnicities that accounts for the range of languages within its borders. Malawi has a number of ethnic groups. These include the major ones, which are the Nyanja, Lomwe, Tumbuka, Yao, Tonga, and Sena, as well as some minor ones, such as the Lambya, Ngonde (Nkhonde), Nyakyusa, Nyiha, and Nsukwa/Ndali. Of these, the Nyanja have traditionally been viewed as constituting the majority group (cf. Kishindo, 1994; Matiki, 1997; Mchombo, 1998; Young, 1949). During the era of colonialism the British recognized the importance of chi-Nyanja. It was a language that could contribute to promoting understanding between them as the rulers and the local population, the ruled, for effective government and administration. As a consequence, the colonial government adopted the use of chi-Nyanja, the language spoken by the Nyanja, as the official language in some parts of the country. To facilitate the learning of the language, it was adopted as an official language by the government, with the justification that "[I]n Nyasaland ... the Nyanja speakers not only outnumber those of other areas, but their dialects have a much longer history of literary use" (Price, 1940: 129).

The adoption of Nyanja as the official language gave the impetus for it to be taught in schools. Further, knowledge of the language was required for government duties. As Hailey observed about the situation in Malawi (then Nyasaland), "Nyanja has been adopted as the official language by the government. Knowledge of it is compulsory for departmental examinations and it is intended to introduce it into all schools after two years instruction in the vernacular" (Hailey, 1938: 75). During the preindependence era, chi-Nyanja and chi-Tumbuka (the language of the Tumbuka) were used in the media and in elementary education.

The inclusion of chi-Tumbuka in the media and in elementary education rested on the recognition of its being the most widely spoken language in the northern part of Malawi. Although the Nyanja have predominated in the central and southern parts of the country, the Tumbuka have traditionally been the dominant group in the north. As noted by Leroy Vail, the Tumbuka "live as subsistence agriculturalists in Zambia and Malawi. In Zambia, they live in the eastern Province's Isoka and Lundazi Districts, while in Malawi, they are found in Chitipa, Karonga, Nkhata Bay, Rumphi, Mzimba and Kasungu Districts of the Northern and Central Regions. Their territory is about 20 000 square miles in extent, with the Luangwa River of Zambia forming their western boundary, Lake Malawi their eastern boundary, the valley of the North Rukuru River (latitude 10° S) their northern boundary, and approximately 12° 30′ S their southern limit" (Vail, 1972: xiii).

The Tumbuka language is bordered by a number of smaller Bantu languages to its north. These include the languages of the Nyiha, Lambya, Sukwa/Ndali, and the Ngonde. In Zambia, Tumbuka is neighbor to Senga and Bisa. To the south, it borders chi-Chewa, the language of the Chewa group. The Chewa are widely scattered, living in Malawi and Zambia.

Although the Chewa were regarded as a subgroup of the Nyanja, the latter also are well represented in Mozambique, with their language, chi-Chewa, considered a dialect variation of chi-Nyanja (cf. Watkins, 1937), political developments in independent Malawi led to a reversal of the roles. With the ascendancy of a nationalist Chewa to the presidency when Malawi gained independence from Britain, subsequently becoming a republic, the roles were reversed, based on basic misconceptions about the distinction between language and dialect (cf. Mchombo, 2005). It was claimed that the Chewa constituted the main group, with chi-Chewa, their language, being the main language. It was the Nyanja who constituted a subgroup of the Chewa, and hence their language, chi-Nyanja, was a dialect of chi-Chewa. Identification of the language was altered in Malawi, from chi-Nyanja to chi-Chewa, with the latter eventually accorded the status of national language (See: Nyanja). With the departure of Kamuzu Banda and altered political circumstances in Malawi, the situation is, yet again, being reversed, with a restoration of chi-Nyanja as the major language of Malawi. Part of the argumentation is that the restoration of this label chi-Nyanja for the language brings Malawi in line with its neighbors. In both Mozambique and Zambia, where the language is one of the major languages, it has always been identified by that label. Politically, the move constitutes a reduction of the dominance of the Chewa in the Malawian political and cultural fabric.

By far chi-Nyanja (henceforth Chinyanja) is the most widely spoken language in Malawi. The resources

devoted to its development and promotion as an aspect of implementation of the language policy that made Chichewa the national language contributed greatly to the enhancement of its diffusion and usage in the country. With the elevation of Chichewa to the status of national language, Chitumbuka, along with other languages, suffered great marginalization. It lost the literary activity and the presence in the mass media that it had previously enjoyed. The profile of Chitumbuka declined after the national language policy was articulated, a policy that created "a situation which resulted in bitter resentment throughout the northern region, a situation made worse by Chewa-speakers' triumphal assertions that other people of the country were cultureless because they had no language" (Vail and White, 1989 183). The language policy thus angered various sections of the population, primarily the Tumbuka, which was to influence the nature of Malawi politics thereafter (Mchombo, 1998).

Of the remaining languages, Tonga is found in an area along the shores of Lake Malawi in an enclave in Nkhata Bay District, between Tumbuka to its north and west and Nyanja to the south. More visible in Malawi than the Tonga are the Yao. They are concentrated along the southern coastline of Lake Malawi, on both the Malawi and Mozambique sides, spreading into parts of southern Malawi. They are more numerous in Mozambique, where they spread into southern Tanzania.

The Lomwe, although at some point viewed as constituting the most populous group after the Nyanja and ahead of the Yao and the Tumbuka, have normally been seen as a spill-over from Mozambique. Concentrated along the southeast border of the Malawi/Mozambique borderline, and spreading westward into areas close to the major commercial city of Blantyre, they have rarely had a profile in the country's linguistic landscape comparable to that of the other ethnic groups. In part this is because during the first census taken in independent Malawi in 1966, most of the Lomwe, fearful of the potential for ethnic isolation and possible political repercussions of that, registered as Chewas. Most spoke Chinyanja/Chichewa, except in their home areas. This contributed toward diminished visibility of their language within the country. It remains the only language of a once major group for which manuals or descriptive grammars are lacking. Even the recent move to include news broadcasts in it, along with the other major languages, has not translated into readily accessible written works in or on the language or generated increased scholarly interest in it. This author intends to have that altered and to stimulate research into this language.

The southern tip of Malawi, spreading into southern Mozambique, is the Lower Shire valley. The Shire River originates from the southern extremity of Lake Malawi. It flows through southern Malawi into Mozambique to join the Zambezi River. The Lower Shire Valley is home to the Sena. They, together with their language, chi-Sena, spread into southern Mozambique, toward the Zambezi River.

The remaining languages of Lambya, Nyakyusa, and Ngonde (Nkhonde), are minority languages spoken in the northernmost parts of the country. Also spoken in northern Malawi is Chindali or Chinsukwa. This is such a less commonly spoken language that it is virtually top on the list of endangered languages in the country. Studies of this and other minority languages are currently being undertaken by individual researchers (e.g., Robert Botne of Indiana University), as well as under the auspices of the Center for Language Studies in Malawi, affiliated with the University of Malawi. One language that has been mentioned as bordering with Chitumbuka in the west is Chinsenga. Although the language is primarily spoken in Zambia, it has some presence in Malawi, in the Malawi/Zambia border areas such as Mchinji (cf. Simango, 1995). In some linguistic surveys of east, central, and southern Africa (e.g., work done by scholars in Mozambique [NELIMO]), this language has been classified as a dialect of Chinyanja.

There is one ethnic group that is traditionally included in the listing of ethnicities in Malawi. This is the Ngoni. There is a significant percentage of the Malawi population who call themselves Ngoni. Moving in from southern Africa, the Ngoni were a conquering nation. They waged war with other ethnic groups, including the Chewa and the Tumbuka. They then settled in some of the places that they had conquered. In fact, it is noted of the Tumbuka that they were not a tribe per se. As indicated by Vail, "the Tumbuka people are historically not members of that discrete entity known commonly as a 'tribe.' This term, as generally used, has implied some sort of unity based on a common language and common cultural traits. Following from this synchronic cultural unity, it was assumed that a particular 'tribe' had a common past and an historical unity. In fact, however, the historical reality is far different, and Tumbuka history is more accurately seen when viewed as the aggregate history of individual clans" (xiv). Other historians have commented that the individual clans that constituted the Tumbuka had well-established dynasties and that they had developed their language, culture, and political and economic institutions during the period of their struggles with the Ngoni who had invaded their land (cf. Matiki, 1997; Pachai, 1973).

Thus, the Ngoni constitute a significant ethnic group that settled in Malawi. However, their language, chi-Ngoni, is not normally recognized in the linguistic map of Malawi because the Ngoni assimilated to either the Chewa in the south or the Tumbuka in the north. Although some of the culture and customs may have been preserved, such as traditional dances, initiation ceremonies marking rites of passage, and so on, the Ngoni adopted the languages spoken in their new habitat. If chi-Ngoni is used at all, it is used primarily during ceremonial occasions. In fact, when used, chi-Ngoni sounds very much a variant of such Nguni languages as Zulu, spoken in southern Africa.

Finally, very little has been said about Nyiha. This is one of the languages that borders with Tumbuka. It does not normally feature among the languages of Malawi because it is spoken primarily in Zambia and makes contact with Tumbuka there.

Malay, a member of the Malayic language group, belongs to the subfamily of the western Malayo-Polynesian languages of the Austronesian language family. Other Malayic variants that have Proto-Malayic as their common ancestor include Minangkabau, Kerinci, Banjar, Iban, and Jakarta Malay (Adelaar, 1992). Northwestern Borneo is thought to be the homeland of the speakers of the proto-language (Adelaar, 1995; Nothofer, 1997; Collins, 1998). About 2000 years ago some of them migrated to eastern Sumatra, while others remained behind and stayed in northwestern Borneo. Some of the latter traveled south to Ketapang and then crossed over to Bangka and Belitung (Nothofer, 1997). Those remaining in the homeland area are the ancestors of speakers of Malayic Dayak languages (e.g., Iban, Selako). The Malays who sailed to Sumatra settled the island's east coast. Some moved on into the interior and to the west coast of southern Sumatra. While Middle Malay, Minangkabau, and Kerinci have inland and west coast variants as their origin, Malay itself developed from isolects spoken on the east coast. Later, Malay speakers from the southeast coast of Sumatra established Malay colonies in the Malay Peninsula. Other Malays returned to west Borneo, where they settled the coastal and riverine areas. The isolects spoken by these relatively recent migrants differ considerably from the isolects of Malays who never left Borneo. Coastal Borneo has other Malay isolects such as Sarawak Malay, Brunei Malay, Kutai Malay, and Banjjar, perhaps as a result of a clockwise settlement that originated in western Borneo (**Figure 1**).

Malay, the native language of the powerful kingdoms along the shores of the Straits of Malacca through which all traders from the west and the east

Thus, the Ngoni constitute a significant ethnic group that settled in Malawi. However, their language, chi-Ngoni, is not normally recognized in the linguistic map of Malawi because the Ngoni assimilated to either the Chewa in the south or the Tumbuka in the north. Later, Malay speakers from the southeast coast of Sumatra established Malay colonies in the Malay Peninsula. Other Malays returned to west Borneo, where they settled the coastal and riverine areas. The isolects spoken by these relatively recent migrants differ considerably from the isolects of Malays who never left Borneo. Coastal Borneo has other Malay isolects such as Sarawak Malay, Brunei Malay, Kutai Malay, and Banjjar, perhaps as a result of a clockwise settlement that originated in western Borneo (Figure 1).

Malay, the native language of the powerful kingdoms along the shores of the Straits of Malacca through which all traders from the west and the east

Figure 1 Map of the Malay-speaking area.

had to sail, was prone to become the means of communication of all those involved in commercial activities in the Indo-Malaysian archipelago. With the development of the spice trade, this language was carried all the way to the Moluccas and to the many other harbor towns of this archipelago. when the Portuguese arrived in the early 16th century, simplified forms of Malay had already spread east and developed into creoles replacing local languages (e.g., Kupang Malay, Ambon Malay, Larantuka Malay). On the Malay Peninsula and on the adjacent southern islands, Malay developed literary varieties at the various royal courts. The most prestigious one was the literary classical Malay of the Riau-Johore kingdom, which had its roots in the literary tradition of the earlier sultanate of Malacca (Sneddon, 2003; Prentice, 1978).

The existence of two standard varieties of Malay, namely Malaysian (called 'Bahasa Melayu' in Malaysia) and Indonesian ('Bahasa Indonesia'), is mainly the result of an agreement reached between the British and the Dutch, who in 1824 drew new boundaries of their colonial territories. The mainland part of the Malay-speaking area became part of the British realm, and Sumatra together with the offshore islands became part of the Dutch realm. The treaty divided the former Riau-Johore Sultanate into two separate entities, with Johore belonging to the British and the Riau archipelago belonging to the Dutch. Because of this political demarcation, the influential Riau-Johore variant of Malay was now spoken in two distinct territories, which were to become Malaysia and Indonesia. Since this prestigious Riau-Johore court language played a major role in the formation of the standard languages of both countries, Malaysian and Indonesian remained closely related and are dialects of one and the same language. The differences between the two are most obvious in the vocabulary. The phonological, morphological, and syntactic differences are few and not very significant. There are a considerable number of cases in which Malaysian borrowed an English word and Indonesian a Dutch word, e.g., *tayar* vs. *ban* 'tire' or *fius* vs. *sekering* 'fuse.' Other variations occur when one of the two national variants has borrowed a European word, while the other one is a retention or an innovation, e.g., Malaysian *dulang* 'tray' (retention) vs. Indonesian *baki* 'tray' (from Dutch *bakje*) or Malaysian *panggung wayang* 'cinema' (innovation) vs. Indonesian *bioskop* (from Dutch *bioscoop*). There are cases when both Malaysian and Indonesian share the some word but with minor phonetic variation, e.g., Malaysian *kerusi*, Indonesian *kursi* 'chair' (from Arabic *kursī*). In some instances the Malay word underwent different semantic changes, e.g., Malaysian *pusing* 'turn, revolve' has the meaning 'dizzy' in Indonesian. Furthermore, Malaysian has borrowed more from Arabic than Indonesian, while Indonesian has undergone considerable Javanese and Jakarta Malay influence.

In Indonesia, the establishment of Malay as the national language was not disputed; its choice was not regarded as favoring any one ethnic group, since ethnic Malays constituted no more than 10% of Indonesia's population. Furthermore, various forms of Malay had long been established throughout the

Indonesian archipelago. In Malaysia, the situation was different. When Malaysia became independent in 1957, Malay became the national langauge and one of the official languages (the other is English). Malay became the only language of education. Since Malay was more or less the exclusive property of the Malays, who made up about 50% of the population, the Chinese and Indian population of Malaysia felt at a disadvantage. A change of the language name from Bahasa Melayu to Bahasa Malaysia was one of the compromises made to comfort the non-Malay population. Later, however, the name Bahasa Melayu was reintroduced. In Malaysia, English still plays in important role and today competes with Malay as the language of instruction; in 1993, English became the language of instruction in universities. The Malaysian government argued that this was done in the interest of science and technology (Sneddon, 2003). Since 2003, secondary schools have taught mathematics and sciences in English. The introduction of English as language of education was based on the government's observation that the knowledge of English among pupils and students had deteriorated dramatically. Many Malays are worried that juxtaposing Malay and English against each other will result in a new linguistic scenario and marginalize the original national language policy.

In 1984 Malay also became the national language of Brunei Darussalam in northeast Borneo and is also called Bahasa Melayu. In this country it is the sole official language. The standard language is lexically much closer to Malaysian. In addition to Bahasa Melayu the state of Brunei also has another Malay variant (Brunei). This variant constitutes the main lingua franca in the coastal regions of Brunei (Nothofer, 1991). Brunei has an official bilingual education policy that preserves the status of Malay but recognizes the importance of English by making it the medium of instruction from the upper primary school onward in almost all subjects.

Malay is also the national language of Singapore and one of its four official languages, along with English, Mandarin Chinese, and Tamil. Malay is a minority language, spoken by not more than 15% of the population. In southern Thailand, more than a million speakers use a Malay variant, Pattani Malay.

Cooperation between Malaysia and Indonesia resulted in the spelling reform of 1972, which removed the differences in the spelling of consonants, e.g., former Malaysian *ch* and Indonesian *tj* are now spelled *c*; former Malaysian and Indonesian *dj* are now spelled *j*. The cultural pact between the countries was intensified in 1972 with the establishment of a council known as the Language Council for Indonesia and Malaysia (MBIM). Its main tasks are to create a common scientific terminology and cooperate closely on matters pertaining to language. In 1986, Brunei Darussalam officially joined as a member of the Council, which took the new name MABBIM.

Malay Phonology

The description of the Malay phonology shown here is that of Standard Malay (SM), as defined by Adelaar (1992: 3). The vowel phonemes of SM are shown in Table 1, and consonant phonemes are shown in Table 2. The consonant */r/* is realized as a velar or uvular fricative and elided word finally by speakers of the traditional Malay areas. It is an apical flap or trill outside these areas and in official Indonesian (Adelaar, 1992: 8).

Table 1 Vowel phonemes in standard Malay

	Front	*Central*	*Back*
High	*i*		*u*
Mid	*e*	*ə*	*o*
Low		*a*	

Diphthongo: *-ay, -aw.*

Malay Morphology

Malay prefixes include: *bər-* 'stative, habitual'; *məN-* 'active, agent focus'; *di-* 'passive, patient focus'; *məmpər-/dipər-* 'causative'; *tər-* 'accidental state, involuntary, agentless, sudden'; and *pəN-*, *pər-*, *pə-* 'actor of the performance, instrument with which the

Language and Speakers

Malayalam, a major literary language of South India with long traditions of literature and scripts, is the main language of the state of Kerala and of the islands of Lakshadweep, which are 200–400 km off the southwest coast of India. Malayalis have migrated to different parts of India and overseas, especially to Malaysia, Singapore, the United States, Canada, the United Kingdom, and Australia. The number of Malayalam speakers in India is 31.83 million. In Kerala, 96% of the total population is composed of the religious majority (comprising Hindus, 58.1%) and the religious minorities (Muslims, 21.3%; Christians, 20.6%); these groups mostly speak Malayalam. Linguistic minorities comprise 5.2% of the population. Kerala has the highest literacy rate in India (90.6% of the population). The number of dailies and periodicals in Malayalam in 2000 was 1505 (according to the *Manorama year book* in 2004).

Language and Speakers

Malayalam, a major literary language of South India with long traditions of literature and scripts, is the main language of the state of Kerala and of the islands of Lakshadweep, which are 200–400 km off the southwest coast of India. Malayalis have migrated to different parts of India and overseas, especially to Malaysia, Singapore, the United States, Canada, the United Kingdom, and Australia. The number of Malayalam speakers in India is 31.83 million. In Kerala, 96% of the total population is composed of the religious majority (comprising Hindus, 58.1%) and the religious minorities (Muslims, 21.3%; Christians, 20.6%); these groups mostly speak Malayalam. Linguistic minorities comprise 5.2% of the population. Kerala has the highest literacy rate in India (90.6% of the population). The number of dailies and periodicals in Malayalam in 2000 was 1505 (according to the *Manorama year book* in 2004).

Etymology and Variant Names

Malayāḷam is a combination of *mala* 'mountain' with any of the following terms: *aḷam* 'the place,' denoting 'the mountain country'; *ālam* 'depth,' representing 'the land that lies between the mountain and the deep ocean'; or *āḷ* 'man,' meaning 'mountain dweller.' The last term may convey the original meaning of *Malayāḷam*, denoting both 'the people,' depicted by word forms such as *malayāḷar*, *malayāḷi*, and *malanāṭṭukāran*, and the region or country, as in the term *malanāṭu*. Early variants include *malayālma*, *malayāyma*, and *mlayāṇma*. *Malayāḷam* may be a later variant. *Lilatilakam*, a famous 14th-century work on the grammar and language of Malayalam, mentions only *kēraḷabhāṣa* to denote the language.

Development of Literature

Malayalam flourished in Kerala amidst continuous contact and convergence with Sanskrit, Prakrit, and Pali; profusely borrowing lexical items from these languages in addition to incorporating loans from Arabic, Persian, Urdu, Syriac, Portuguese, Dutch, Hindi, and English. The early development of Malayalam was considerably influenced by Sanskrit, the language of scholarship, and Tamil, the language of administration; eventually, Malayalam evolved in written documents and literature. The Brahmin contact made profound impact in adapting several Indo–Aryan features into Malayalam. Malayalam has a recorded literary history of over eight centuries; the earliest document, the Vałappaḷḷi inscription of Rajasekhara, dates to the 9th century. The early literature developed through three different traditions: (1) the Tamil tradition of *pāṭṭu*, the classical songs depicted in the first literary work, *Ramacaritam*, (2) the Sanskrit tradition of *maṇipravāla*, a literary innovation portraying a harmonious blend of *bhāṣa* and *Samskṛita* (i.e., the native language and Sanskrit – for instance, *Vaiśikatantram*), and (3) the native tradition of producing folk songs and ballads predominantly concerning indigenous elements. *Bhasakautiliyam* is the earliest prose written in simple language. All three traditions belong to the 12th century. Modern Malayalam literature is rich in fiction, poetry, prose, drama, short stories, biographies, and literary criticism.

Writing System

The early Malayalam writing system had evolved from Vaṭṭeluttu, traceable to the Pan-Indian Brahmi script; this system continued for a long period, eventually adding symbols from Grantha script to represent Indo-Aryan loans. The writing is based on the concept of the *akṣara* 'graphic syllable,' wherein the graphic elements have to be read as units, although the individual vowels and consonants are easily recognizable. The script reformation implemented in the 1970s made a reduction of the less frequent conjunct consonants and combinations of the vowel *u* with different consonants, to make a simpler writing scheme. The orthography is largely phonemic, with separate script for each phoneme (with a few exceptions). The dental and alveolar single nasals (*n* and *n*) are depicted by the same script, as are their long counterparts. The direction of writing for several scripts is clockwise. In a few cases, the direction is clockwise plus anticlockwise or vice-versa within a single letter. Malayalam scripts bear simple to complex allographic representations. Geminated consonants and heteroelemental consonant clusters are marked differently by writing the consonants side by side, or one above the other. Additionally, there are other combinations of consonants that seldom follow regular patterns in graphemic depiction. The six consonants *m*, *n*, *ṇ*, *r*, *l*, and *ḷ* in word-final positions have separate symbols for writing.

Grammatical Tradition

Malayalam grammatical tradition commenced with the 14th-century *Lilatilakam*. The European contributions in the early 18th century were of great importance, especially Hermann Gundert's *Malayāḷabhāṣāvyākaraṇam* (1851, 1868). The 19th century saw the publication of grammatical treatises by a few native scholars, viz., George Mathan (*Malayālmayuṭe vyākaraṇam*), Kovunni Nedungadi (*Kēraḷakoumudi*; 1878), and some others, but the most widely used work was that of A. R. RajaRaja Varma, the *Kēraḷa pāṇinīyam* (1896). This was followed by L. V. Ramaswamy Iyer's profound contribution to various aspects of Malayalam linguistics in 1925. The past four decades have witnessed the production of considerable work based on modern linguistic theories and descriptive techniques applied both to various written texts belonging to different centuries, ranging from *Ramacaritam* to the 16th-century *Adhyatma Ramayanam*, and to regional, caste, communal, and tribal dialects, with the ultimate goal of preparing a historical grammar for Malayalam that is still a desideratum (much of this work can be found in the Ph.D. dissertations by scholars in the Department of Linguistics, University of Kerala).

Dialect Variation

Malayalam dialect variations are discernible with respect to phonetic, phonological, grammatical, semantic, and lexical levels and in intonation patterns along the parameters of caste, community, region, social stratum, education, occupation, style, and register. The speech forms of Travancore, Cochin, South and North Malabar, and the Lakshadweep islands show considerable differences. Among the 48 tribal languages in the hilly tracts of Kerala, many are dialects of Malayalam and a few belong to one or the other of South Dravidian languages.

The first systematic dialect survey of Malayalam was based on a single speech community, the Ezhava/Tiyas groups living throughout Kerala; the survey was completed in 1968, demarcating 12 major dialect areas (Subramoniam, 1974). This was followed by the Nair and Harijan dialect surveys. About 600 dialect maps were prepared concerning the Ezhava/Tiyas and Nair castes, along with frequency charts of the variants, showing differences with regard to 300 diagnostic lexical items. Copies of these maps are preserved in the collections of the Department of Linguistics, University of Kerala, and the International School of Dravidian Linguistics, Thiruvananthapuram, Kerala. Among several dialect variations, the occurrence of *y* in place of *ł* is commonplace, as in *pałam* > *payam* 'fruit,' but the occurrence of *t* (*ketakku* 'east') is a rare feature found in the northern part of Kasargod. Initial *v*/*b* alternation, as in *v*/*barin* 'come' and *v*/*bāppa* 'father,' is a distinct feature of Muslim speech throughout Kerala and Lakshadweep, but in Cannanore district this change is found in the speech of other castes, demonstrating the overlap of caste, communal, and regional traits. Word-final *n*/*m* alternation is a feature of the Muslim dialect of Ernad and Lakshadweep, as in *nēran*/*nēram* 'time.' Present tense markers *-anRa* and *-uṇṭa*, as in *kottanRa* 'chops' and *iṭuṇṭa* 'places,' is a peculiarity of the PaRaya speech of Kasargod; *-aṇṭa*, as in *bayaṇṭa* 'comes,' is found in the Muslim dialect of Lakshadweep.

The literary dialect is almost uniform. The language that is used in newspapers, in mass media, and in formal situations, which is largely understood by the majority of the people irrespective of caste, community, and region, is considered to be the standard variety. A standard colloquial is slowly evolving.

Genetic Affiliation

Malayalam shows affinity to Tamil, Kota, Toda, Irula, Badaga, Kodagu, Kannada, and Tulu, all of which belong to the South Dravidian branch of the Dravidian family. However, the affinity with Tamil is greater, since Malayalam emerged from Proto-Tamil–Malayalam; divergence occurred over a period of four or five centuries, from the 8th century onward, and distinct languages, separate from Tamil, were established.

Three distinctive features of Proto-Tamil–Malayalam include (1) *k-* > *c-* before front vowels, whether followed by a retroflex or not, (2) **e*, **o* > *i*, *u* before a derivative suffix beginning with *a*, and (3) the presence of the accusative suffix *-ai*. The features that distinguish Malayalam from Tamil are (1) progressive assimilation of nasal + stop > nasal + nasal except in retroflexes and labials, (2) loss of person–number–gender in finite verbs, (3) negative periphrastic construction with *illa*, and (4) prohibitive construction with infinitive + *arutu*.

Characteristic Features

Phonology

Five vowels with length contrast, *i*, *e*, *a*, *o*, and *u*, occur in the literary and spoken dialects. Two diphthongs, *ai* and *au*, occur in the literary language. An onglide *y* and *v* occur word initially in front and back vowels, respectively, in pronunciation. Vowels occur in all positions except for short *o*, word finally. The *u* is pronounced as a high back rounded vowel when it occurs initially, medially without length in the first syllable, and with length finally, whereas it is pronounced as a lower high back unrounded vowel (*samvrutookaaram*) medially except in the first syllable and without length word finally.

Single voiceless stops (except in clusters with homorganic nasals) are pronounced with voicing (with or without slight fricativization) when occurring intervocalically; voiceless stops preceded by homorganic nasals are pronounced with slight voicing. Generally, aspirated plosives lose aspiration in pronunciation. Only six consonants, *m*, *n*, *ṇ*, *r*, *l*, and *ḷ*, can occur word finally; *n* occurs medially either with length or in clusters. All other consonants can occur word initially and medially. Voiceless stops occur medially with length and in clusters, except with homorganic nasals. For consonants, length contrast occurs only medially; *r*, *s*, *ś*, *ṣ*, *h*, and *ł* do not geminate.

Morphophonemics

The sandhi rules (a systematic blend of words; Sanskrit *sandhi* 'to join') fall under two categories, internal and external, the former operating within a word and the latter operating between words; the

rules may operate in either category or in both categories (sandhis). For example, for a vowel V, the rule V1 + V2(V2) + V2(V2) operates only in close juncture: *āyi + illa > āyilla* 'did not become.' The following examples show other sandhi blends:

i e a	+	v vv	>	i e + y + a	v vv	(internal and external)
kuṭṭi	+	uṭe	>	kuṭṭiyuṭe 'child of '		
nalla	+	āḷu	>	nallayāḷu 'good person'		
tala	+	alla	>	talayalla 'head not'		
u	+	v(v)	>	u + v +	v(v)	(internal and external)
rāmu	+	um	>	rāmuvum 'Ramu also'		
kuru	+	āyi	>	kuruvāyi 'seed become'		
l/ṇ	+	n	>	ṇṇ (external)		
toḷ	+	nūRu	>	toṇṇūRu 'ninety'		
kaṇ	+	nīru	>	kaṇṇīru 'tears'		
m/n/ṇ	+ STOP		>	(homorganic nasal + stop)		
cem	+		tāmara	> centāmara 'lotus'		
pin	+		tuṇa	> pintuṇa 'support'		
peṇ	+		kuṭṭi	> peṇkuṭṭi 'girl'		

Morphology

Noun stems fall under three categories, viz., personal pronouns (first person, inclusive and exclusive), second person, and reflexives. Demonstrative base + gender number marker constitutes third-person pronouns, as in *av-an* 'he,' *avaḷ* 'she,' and *av-ar* 'they.'

Numerals consist of adjectival and case bases. Number markers are *-n* (gender singular), *-m* (gender plural), *ñān* 'I,' *nammal* 'we (inclusive),' *-tu* (non-gender-neutral singular), and *atu* 'that.' Examples of gender markers are *-n*, *-ān*, and *-an* (masculine) and *-ḷ*, *-atti*, and *-āṭṭi* (feminine). Plural suffixes are *-aḷ* and *-kaḷ*.

Nominative case has no marker; accusative uses *-e* and *-a*, dative uses *-u* and *-kku*, and instrumental uses *-aal* (in literary Malayalam; in dialects, postposition *kontu* 'with' is used). Sociative case uses *-ōṭu* and locative case uses *-il*.

Verbs do not distinguish person–number–gender. Both finite and nonfinite verbal forms consist of a verb stem followed by verbal suffixes, which take (or can take) tense markers. A few verbs do not take tense but can take negative markers (*illa* 'no,' *alla* 'not,' and *arutu* 'do not'). Verbs fall into two groups, intransitive and transitive. Some of the former are transitivized morphologically in three ways: (1) by suffixing the markers *-tt-* and *-kk-* to the intransitive verb stem (*iru* 'to sit,' *iru-tt-* 'to make to sit'; *oṭi* 'to break,' *oṭi-kk-* 'to make to break'), (2) by geminating the stem-final stops (*aaṭ-* 'to become,' *ākk-* 'to make to become'; *aaṭ-* 'to swing,' *aaṭṭ-* 'to make to swing'; *kēr-* 'to climb, *kēRR-* 'to make to climb'), and (3) stem finally (nasal + nasal > homorganic stop + homorganic stop (*uRaṅṅ-*'to sleep,' *uRakk-* 'to make to sleep'). Two causative markers, *-i-* and *-ppi-*, can occur simultaneously within a verb, as in *paRay-i-ccu* 'caused to say,' *paRay-i-ppi-ccu* 'to cause to say.'

Three-way distinctions in tense occur, i.e., present, future, and past. Examples are *-unnu* (present tense) and *-um* (future tense), as in *var-unnu* 'comes' and *var-um* 'will come.' All vowel-ending stems take link morph *-kk-* before present and future markers, as in *paṭi-kk-unnu* 'learns' and *paṭi-kk-um* 'will learn.' The verb stem *vēṇ-*is peculiar in that it takes the future tense marker-*am* (*vēṇ-am* 'will need') but does not take either the present or the past tense suffix. There are several past tense markers: the vowel ending *-i* (*pāṭi* 'sang') and nasals *-nn-*, *-ññ-*, *-ṇ-*, and *-nt-* (*iru-nnu* 'sat,' *kara-ññu* 'wept,' *tā-ṇu* 'drowned,' *no-ntu* 'pained,' and *ve -ntu* 'boiled'; only these last two verbs take the past tense *-nt-*).

Stops are *-t-*, *-ṭ-*, *-R-*, and *-c-* (*eṭu-ttu* 'took,' *kaṇ -ṭu* 'saw,' *pe-RRu* 'delivered,' and *aṭi-ccu* 'beat'). Negative suffixes are *-ātt-* before the relative participle marker *-a* (*var-ātt-a* 'that which did not come), *-āt-* before the verbal participle marker *-e* (*var -āt -e* 'having not come'), and *-a*, which freely varies with *-ā* (*vē-ṇṭa*(*a*) 'not needed'); *-ān* denotes the purposive infinitive (*paRay-ān* 'saying').

The vowel-ending stems can be used as imperatives (*paRa* '(you) tell,' *nōkku* '(you) look'), but are less polite in speech than *-ū* is (the more polite forms are *paRay-ū* and *nōkk-ū*). The optative marker is *-aṭṭe*, as in *var-aṭṭe* 'let (him) come.'

Syntax

Three major types of sentences, simple, complex, and compound, can be discerned. A simple sentence consists of the subject noun and predicate verb, as in *raaman varunnu* 'raman comes.' A nominal sentence in which both the subject and the predicate are nouns is seen in *atu maram* 'that is tree.' The finite verb *aanu* is optional. Malayalam word order is not rigid. Subject–object–verb is the usual order. A noun or noun phrase can be the subject in a sentence. A noun phrase (NP) is expandable by modifiers, the structure of which is ± possessive ± demonstrative ± numeral Adj ± Adj + NP, as in *enRe ā oru nalla peena* 'my that one good pen' 'that good pen of mine.' A noun phrase can be expanded by a relative participle, nouns, case base, and clitics, as in *ceyta kāryam* 'thing done,' *kaykāryam* 'handling the affairs,' *tankaaryam* 'one's own affair,' *kāṭṭukōli* 'jungle fowl,' and *piRRe divas am* 'next day.'

Nouns/noun phrases can form the direct or indirect object. If the direct object is an animate noun, the

accusative case suffix *-e* is added; if the direct object is an inanimate noun, the case suffix is dropped. The indirect object takes the dative case, as in *avaḷ sītaykku* (indirect object) *oru pūccaye* (direct object) *kot'uṭṭu* 'she gave a cat to Sita.' Verbs/verb phrases are expanded by verbal participles, auxiliary verbs, or adverbial clitics, as in *talayil cumaṭu veccukoṭuttu* 'placed a bundle on the head' and *patukke pooyi* 'slowly gone.'

Interrogative sentences can be formed by adding the interrogative clitic, which would yield 'yes' or 'no' types of answers (*avaḷ sītayānō* 'is she Sita?'). This can also denote doubt. After the defective verbs *illa* and *alla*, the interrogative particle *-ee* is added (*illee*, *allē*, 'is it not'). Interrogative words such as *aaru* 'who,' *eetu* 'which,' and *entu* 'what' can be added to form sentences, as in *āru paRaññu* 'who told', *ētu kāryam* 'which subject,' and *entu vēṇam* 'what (do you) want.' Negative sentences are formed either by negativizing the verb phrase by using morphological negative markers, or by negation of the sentence or verb phrase by using defective verbs such as *illa* and *alla* (*pōyi* 'went,' *pōyilla* 'did not go,' *itu pēna āṇu* 'this is pen,' *itu pēna alla* 'this is not pen,' *āhāram uṇṭu* '(there) is food,' *āhāramilla* '(there) is no food').

Malayo–Polynesian Languages

M Ross, The Australian National University, Canberra, Australia

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The term 'Malayo–Polynesian' today denotes the largest of the ten putative primary subgroups of the Austronesian language family (Blust, 1999). Malayo–Polynesian (MP) embraces perhaps 1100 languages, while the other nine groups consist only of the surviving fourteen Formosan languages of Taiwan (*see* **Formosan Languages**). Until Father Wilhelm Schmidt invented the term 'Austronesian' in 1899, however, 'Malayo–Polynesian' denoted the whole Austronesian language family. Its German equivalent, *malayisch-polynesisch*, was first used in print by Franz Bopp in 1841 (it is often wrongly attributed to Wilhelm von Humboldt, but is not found in his writings). 'Malayo–Polynesian' was in use with this meaning in English by the 1870s, but who first used it to refer to the language family is unclear (Ross, 1996). It continued to be used as a synonym for Austronesian until the 1970s, and is occasionally still used in this sense today.

In 1977 Robert Blust showed that the primary division of Austronesian was into several subgroups of languages spoken in Taiwan and a single subgroup which he labeled 'Malayo–Polynesian' and which includes all the Austronesian languages spoken outside Taiwan: the Austronesian languages of the Philippines, Southeast Asia, Madagascar, the Indo-Malaysian archipelago, New Guinea, Island Melanesia, Micronesia, and Polynesia. This is the sense of 'Malayo–Polynesian' in the remainder of this article. Some scholars prefer the term 'Extra-Formosan' in its place. Clearly the potential for overlap between this and a discussion of Austronesian languages is great, and the reader is referred to **Austronesian Languages: Overview** for further information.

The Integrity of the Malayo–Polynesian Subgroup

How do we know that all Austronesian languages outside Taiwan belong to a single subgroup? To determine a family tree we first compare the languages of the family and reconstruct the protolanguage from which they are descended, in this case Proto Austronesian (PAn). Then we identify subgroups of languages whose members share a set of innovations relative to PAn. We infer that the innovations are shared because they have been inherited from a single interstage language. This is far more probable than

accusative case suffix *-e* is added; if the direct object is an inanimate noun, the case suffix is dropped. The indirect object takes the dative case, as in *avaḷ sītaykku* (indirect object) *oru pūccaye* (direct object) *kot'uṭṭu* 'she gave a cat to Sita.' Verbs/verb phrases are expanded by verbal participles, auxiliary verbs, or adverbial clitics, as in *talayil cumaṭu veccukoṭuttu* 'placed a bundle on the head' and *patukke pooyi* 'slowly gone.'

Malayo–Polynesian Languages

M Ross, The Australian National University, Canberra, Australia

Introduction

The term 'Malayo–Polynesian' today denotes the largest of the ten putative primary subgroups of the Austronesian language family (Blust, 1999). Malayo–Polynesian (MP) embraces perhaps 1100 languages, while the other nine groups consist only of the surviving fourteen Formosan languages of Taiwan (*see* **Formosan Languages**). Until Father Wilhelm Schmidt invented the term 'Austronesian' in 1899, however, 'Malayo–Polynesian' denoted the whole Austronesian language family. Its German equivalent, *malayisch-polynesisch*, was first used in print by Franz Bopp in 1841 (it is often wrongly attributed to Wilhelm von Humboldt, but is not found in his writings). 'Malayo–Polynesian' was in use with this meaning in English by the 1870s, but who first used it to refer to the language family is unclear (Ross, 1996). It continued to be used as a synonym for Austronesian until the 1970s, and is occasionally still used in this sense today.

In 1977 Robert Blust showed that the primary division of Austronesian was into several subgroups of languages spoken in Taiwan and a single subgroup which he labeled 'Malayo–Polynesian' and which includes all the Austronesian languages spoken outside Taiwan: the Austronesian languages of the Philippines, Southeast Asia, Madagascar, the Indo-Malaysian archipelago, New Guinea, Island Melanesia, Micronesia, and Polynesia. This is the sense of 'Malayo–Polynesian' in the remainder of this article. Some scholars prefer the term 'Extra-Formosan' in its place. Clearly the potential for overlap between this and a discussion of Austronesian languages is great, and the reader is referred to **Austronesian Languages: Overview** for further information.

The Integrity of the Malayo–Polynesian Subgroup

How do we know that all Austronesian languages outside Taiwan belong to a single subgroup? To determine a family tree we first compare the languages of the family and reconstruct the protolanguage from which they are descended, in this case Proto Austronesian (PAn). Then we identify subgroups of languages whose members share a set of innovations relative to PAn. We infer that the innovations are shared because they have been inherited from a single interstage language. This is far more probable than

the alternative assumption – that the innovations have occurred independently in each language that reflects them.

All Austronesian languages outside Taiwan reflect certain phonological innovations relative to PAn, and we infer that they occurred in a single interstage language which Blust named Proto Malayo-Polynesian (PMP). These innovations are enumerated here (from Blust, 1990) with minimal discussion and examples.

A. PAn *t and *C merged as PMP *t.
B. PAn *L and *n merged (with some unexplained exceptions) as PMP *n.
C. PAn *S became a glottal spirant of some kind, but did not merge with *h.

Innovation A is illustrated below, where PAn *t and PAn *C (which remain separate in the Formosan language Rukai) are merged in MP languages, exemplified by Itbayat, a language of the Batanes islands between Taiwan and Luzon:

PAn **tuLa* 'freshwater eel' (Rukai *tola*) > PMP **tuna* (Itbayat *tuna*)
PAn **pitu* 'seven' (Rukai *pito*) > PMP **pitu* (Itbayat *pitu*)
PAn **Caliŋa* 'ear' (Rukai *tsa[iŋa*) > PMP **taliŋa* (Itbayat *taliña*)
PAn **maCa* 'eye' (Rukai *matsa*) > PMP **mata* (Itbayat *mata*)

In innovation B, PAn *L and *n merged as PMP *n:

PAn **qaLup* 'hunt' (Rukai *alopo*) > PMP **qanup* (Itbayat *anup*)
PAn **wanan* 'right (hand)'(Rukai *vanan*) > PMP **wanan* (Itbayat *wanan*)

Innovation C is reflected in

PAn **duSa* 'two' (Rukai *dosa*) > PMP **duha* (Itbayat *duha*).

A major set of innovations in pronouns involved a 'politeness shift' (Blust, 1977). Just as the English plural pronoun *you*, used as a polite form of address, eventually displaced singular *thou*, so PMP underwent a set of changes in pronouns which were also related to politeness (for details see Ross, 2002: 51). No MP language reflects forms that predate the shift.

PMP added to the verbal system the prefixes **paN*-(distributive), **paR*-(durative, reciprocal) and **paka*-(aptative, potential) (Ross, 2002: 49–50). These are widely reflected in the languages of the Philippines and the western part of the Indo–Malaysian archipelago, and are preserved in fossilized form in many languages elsewhere in the MP subgroup.

History and Subgrouping

How did it come about that all Austronesian languages outside Taiwan belong to a single subgroup while perhaps nine coordinate groups are represented in Taiwan itself? The obvious answer is that PAn was spoken in Taiwan and diversified into a group of languages there. Speakers of one of these languages left Taiwan, presumably for the northern Philippines. Their language underwent the innovations noted above, becoming the language we call PMP.

Archaeological dating suggests that the culture that spoke PAn flourished in Taiwan around 3000 B.C. and that the migration to the Batanes islands or Luzon which led to the genesis of PMP occurred around 2000 B.C. The descendants of PMP speakers evidently spread, mostly south and then eastward, at an astonishing speed, colonizing the Philippines, the Indo-Malaysian archipelago, parts of coastal New Guinea, and the Bismarck Archipelago in the northwest of Island Melanesia within about 500 years, by 1500 B.C. This history is reflected in the tree diagram of the Austronesian family (see **Figure 1**). This shows some 20 to 25 groups of western MP languages, spoken in the Philippines and the western part of the Indo-Malaysian archipelago, with outliers on Hainan, in the Vietnamese highlands, on the islands along the western coast of Thailand and Myanmar, and on Madagascar (see **Figure 2**). The migration of MP speakers to Madagascar was a much later event (Adelaar, 1991). Adelaar (2004) provides a listing of western MP groups which reflects current understanding. Although there are frequent references in the literature to 'Western Malayo–Polynesian,' there was never a 'Proto Western MP,' as western MP languages as a whole share no innovations. The similarities among western MP languages, such as they are, reflect shared retentions from PMP. The fact that the tree shows so many coordinate branches reflects the rapidity with which MP speakers occupied the region. They were agricultural people – rice growers – and probably encountered little significant opposition from the small populations of hunter-gatherers who had previously occupied these territories.

There is reasonable evidence in the form of shared innovations that all MP languages in the regions labeled on the map as Central Malayo–Polynesian (CMP), South Halmahera/West New Guinea (SHWNG) and Oceanic are descended from a single language, shown on Figure 1 as Proto Central/Eastern Malayo-Polynesian (PCEMP) (Blust, 1993). However, the set of innovations that defines this grouping is not nearly as substantial as the set defining MP (see above), and we must infer that the period for which

Figure 1 Austronesian family tree.

PCEMP speakers remained an integrated speech community was short. The conventionally accepted family tree of Austronesian languages (originally proposed by Blust, 1977) gives PCEMP two daughters, 'Proto CMP' and 'Proto Eastern MP.' The status of both is doubtful. There is agreement among scholars today that PCEMP diversified, apparently rapidly, into a dialect network, and that the Eastern Malayo–Polynesian languages broke away from that network, probably as the dialects of the network were achieving the status of separate languages. There is no significant evidence, however, that there was ever a discrete Proto CMP (for more details, see Ross, 1995).

The existence of Proto Eastern MP is also questionable, and it is possible that it was simply a peripheral section of the Central/Eastern MP dialect network (Ross, 1995; Adelaar, 2004). However, there is much less doubt about Proto SHWNG, the ancestor of a small group of languages in the south of Halmahera and scattered around the Bird's Head Peninsula of New Guinea, and no doubt at all about Proto Oceanic.

Proto Oceanic was the ancestor of the MP languages of New Guinea other than those belonging to SHWNG (see map) and of all the MP languages of Island Melanesia, Polynesia, and Micronesia other than Chamorro (Guam) and Palauan (Belau). The Oceanic languages share a striking set of innovations, larger than the set for Proto MP itself. These innovations were first recognised by Dempwolff (1937) in Volume 2 of his pioneering work on Austronesian (*see* **Austronesian Languages: Overview**) and have undergone various modifications since as the result of further research (Lynch *et al.*, 2002: 63–67).

The history represented by the varying strengths of the nodes in the Austronesian family tree diagram (Figure 2) shows a period of relative stability during which Proto MP developed from the speech of those who emigrated from Taiwan, followed by 500 years of extraordinary settlement activity which culminated in the arrival of MP speakers in the Bismarck Archipelago. Here there seem to have been a few more centuries of relative stability, during which Proto Oceanic developed into a language that was at least phonologically and lexically rather different from its sisters around the Bird's Head.

Why the apparent halt in settlement activity? There were perhaps two reasons. First, New Guinea was already inhabited by Papuan speaking agriculturalists (*see* **Papuan Languages**) with much greater population densities than their hunter-gatherer neighbors to the west, and there was little space for the newcomers. Second, there probably was continued settlement activity during the development of Proto Oceanic, but no further than the Solomon Islands, to the east of which there is a substantial sea gap (Pawley, 1981).

There is agreement among many linguists and archaeologists (but not all) working in Island Melanesia that Proto Oceanic was the language of the Lapita Culture, a group that produced distinctive pottery and exploded eastwards into the Pacific from about 1300 B.C. Island Melanesia (the Bismarck Archipelago, Solomon Islands, Vanuatu, New Caledonia, and Fiji), Tonga, and Samoa were all settled within a few hundred years (Kirch, 1997). A linguistic puzzle in this story is that Proto Polynesian, the Oceanic language ancestral to Tongan, Samoan, and the 40 or so languages of scattered Polynesian communities is structurally rather different from other Oceanic languages, yet there is no obvious hiatus in the archaeological record during which these differences might have developed. It is reasonably

Figure 2 The Austronesian family and major Malayo–Polynesian language groups.

certain, however, that Proto Polynesian or an immediate ancestor developed in the northeastern islands of Fiji (Geraghty, 1983).

The Structures of Malayo–Polynesian Languages

MP languages show an extraordinary structural diversity. General accounts can be found in Lynch *et al.* (2002: 34–53) for Oceanic languages and Himmelmann (2004) for other MP languages. The languages of the Philippines and parts of northern Borneo, northern Sulawesi, and Madagascar largely retain the structure of PAn (*see* **Austronesian Languages: Overview; Formosan Languages**). The western MP languages of Vietnam, Hainan, and the Thailand/Myanmar islands show the influence of Mon-Khmer languages. In the western MP languages of Malaysia and western Indonesia we find a complex set of developments in which the PAn voice system is much reduced but applicatives take over much of its functional load (Ross, 2002). The CMP, SHWNG, and Oceanic languages (other than Polynesian) have a broad typological similarity, but with many variations. Most of these languages have lost all trace of voice and have subject-referencing verbal prefixes or proclitics. How this system arose from systems reflected in western MP languages is traced by Lynch *et al.* (2002: 57–63). Klamer (2002) describes CMP language structures, Ross (2004) those of non-Polynesian Oceanic languages.

Further References

The MP family is vast, and the serious enquirer will need to look beyond this article. Detailed maps of the locations of MP languages and their dialects are found in Wurm and Hattori (1981–1983), although it is not a reliable source for subgrouping. Adelaar and Himmelmann (2004) is the major reference for MP languages other than Oceanic, Lynch *et al.* (2002) for Oceanic languages. Both works also include a large collection of grammar sketches of a sample of languages. Tryon (1995) is an extensive comparative lexicon.

Associated with the historical study of MP languages, especially of Oceanic, is a solid body of work on culture history. Ross *et al.* (1998; 2003) are the first two of five volumes in which the terminologies used by Proto Oceanic speakers are reconstructed, following more piecemeal work on the lexicons of MP languages in general (Pawley and Ross, 1994) and work on MP culture history by scholars in various disciplines (Bellwood *et al.*, 1995). Pawley and Ross (1993) is a short survey mostly of MP historical linguistics and cultural history.

Malaysia: Language Situation

H O Asmar

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous editions, volume 5, pp. 2351–2353, © 1994, Elsevier Ltd.

Malaysia, which consists of Peninsular Malaysia, Sabah, and Sarawak (the latter two situated on Borneo), has from the beginnings of recorded time been a multilingual region, with its indigenous population belonging to different linguistic groups. This situation has been intensified with colonialism, immigration, and the nation's language policy.

Language Policy

The national language policy of Malaysia states that Malay is the national and official language. It is written in Arabic and Roman scripts, but it is the latter that is the official writing system.

Malay is also the main medium of instruction, which means that there are other language mediums allowed in the education system of the country: Arabic (Arabic, Standard) in Islamic schools, and Mandarin (Chinese, Mandarin) and Tamil in the national-type schools (those using a language other than the national language as medium of instruction, as opposed to national schools that use Malay).

The national-type schools are required to teach Malay as a compulsory subject. All national and national-type schools are required to teach English, which has been given the status of a second language.

'Pupils' own languages' (POL), that is, mother tongues, are taught in national schools if there is a request from at least 15 pupils to form a class. The POL classes so far are for Mandarin, Tamil, and Iban. Foreign languages such as Japanese and French are taught in certain secondary schools.

The multilingual nature of the country, supported by the education system, has made Malaysians bilingual. A great majority of non-Malay Malaysians know at least two languages: their own and Malay. With English, they become trilingual. There are monolinguals among the Malays, but most are bilingual at least, with English or Arabic as their second language.

Radio Malaysia provides channels for Malay, English, Mandarin, and Tamil. The Sarawak local station broadcasts programs in Mukah Melanau (Melanau) and Iban, while the one in Sabah provides programs in Bajau Darat (Sama, Southern) and Tengara Dusun. Certain local stations in Peninsular Malaysia broadcast programs in two aboriginal-languages, Temiar and Semai. TV Malaysia has programs in Malay, English, Mandarin, and Tamil.

The policy has made Malay and English primary or high languages in the educational, social, and professional lives of the Malaysians. It has also made almost 80% of Malaysians literate in Malay.

Indigenous Languages

The indigenous languages belong to two different stocks: Austronesian and Austroasiatic.

Austronesian Languages

Malay, which is the mother tongue of about 45% of the total population of Malaysia is Austronesian. Native Malay speakers are found in Peninsular Malaysia and the coastlands of Sabah and Sarawak.

The other Austronesian languages are native to Sabah and Sarawak only. A modest estimate of the number of these languages is about 100. 'New' languages are being discovered all the time. What had previously been termed dialects may be found to be

Malaysia: Language Situation

This article is reproduced from the previous editions, volume 5, pp. 2351–2353, © 1994, Elsevier Ltd.

Malaysia, which consists of Peninsular Malaysia, Sabah, and Sarawak (the latter two situated on Borneo), has from the beginnings of recorded time been a multilingual region, with its indigenous population belonging to different linguistic groups. This situation has been intensified with colonialism, immigration, and the nation's language policy.

Language Policy

The national language policy of Malaysia states that Malay is the national and official language. It is written in Arabic and Roman scripts, but it is the latter that is the official writing system.

Malay is also the main medium of instruction, which means that there are other language mediums allowed in the education system of the country: Arabic (Arabic, Standard) in Islamic schools, and Mandarin (Chinese, Mandarin) and Tamil in the national-type schools (those using a language other than the national language as medium of instruction, as opposed to national schools that use Malay).

The national-type schools are required to teach Malay as a compulsory subject. All national and national-type schools are required to teach English, which has been given the status of a second language.

'Pupils' own languages' (POL), that is, mother tongues, are taught in national schools if there is a request from at least 15 pupils to form a class. The POL classes so far are for Mandarin, Tamil, and Iban. Foreign languages such as Japanese and French are taught in certain secondary schools.

The multilingual nature of the country, supported by the education system, has made Malaysians bilingual. A great majority of non-Malay Malaysians know at least two languages: their own and Malay. With English, they become trilingual. There are monolinguals among the Malays, but most are bilingual at least, with English or Arabic as their second language.

Radio Malaysia provides channels for Malay, English, Mandarin, and Tamil. The Sarawak local station broadcasts programs in Mukah Melanau (Melanau) and Iban, while the one in Sabah provides programs in Bajau Darat (Sama, Southern) and Tengara Dusun. Certain local stations in Peninsular Malaysia broadcast programs in two aboriginal-languages, Temiar and Semai. TV Malaysia has programs in Malay, English, Mandarin, and Tamil.

The policy has made Malay and English primary or high languages in the educational, social, and professional lives of the Malaysians. It has also made almost 80% of Malaysians literate in Malay.

Indigenous Languages

The indigenous languages belong to two different stocks: Austronesian and Austroasiatic.

Austronesian Languages

Malay, which is the mother tongue of about 45% of the total population of Malaysia is Austronesian. Native Malay speakers are found in Peninsular Malaysia and the coastlands of Sabah and Sarawak.

The other Austronesian languages are native to Sabah and Sarawak only. A modest estimate of the number of these languages is about 100. 'New' languages are being discovered all the time. What had previously been termed dialects may be found to be

heterogeneous languages, and single language may turn out to be a subfamily of languages.

Based on information available, the languages of Sabah and Sarawak may be listed according to subfamilies of single languages. Most of them are known by the names of the places where they are located.

Languages of Sabah

1. *Dusun/Kadazan subfamily*: Papar, Dumpas, Bisayah (Bisaya, Sabah) Lotud, Tatana, Kuijau, Rungus, Timur, Tengah (Seko Tengah) (with the well-known dialects of Ranau, Bundu Tuhan, Penampang/Tengara, Tambunan), Keningau (Keningau Murut), Tempasu (Dusun, Tempasuk); Sugut (Dusun, Sugut).
2. *Murut subfamily*: Tagal (Tagal Murut) Tiulon, Beaufort (Dusun, Central), Timugon (Timugon Murut), Rundum (Tagal Murut), Takapan & Sook (Paluan) Nabay, Baukan.
3. *Paitan subfamily*: Lingkabau (Tombonuwo), Lobu, (Keningau Murut) Abai Sungai, Tambanua (Tombonuwo) Ulu Kinabatangan.
4. *Bajau subfamily*: Bajau Darat and Bajau Laut (Sama, Southern).
5. *Ida'an or Begahak subfamily* (also known as Orang Sungai): located in Lahad Datu, Sandakan, and Kinabatangan.
6. Suluk (Tausug) in Semporna and Kinabatangan.
7. Banggi (Baujau, West Coast) in the Banggi Island.
8. Illanun (I lanun) in Kota Belud.
9. Lun Dayeh in the western part of Sabah, bordering Sarawak.
10. Tidong (Kalabakan) in Labuk Sugut, Sandakan, and Tawau.

Languages of Sarawak

1. *Bidayuh subfamily*: Biatah, Bau, Jago (Jagol), Serian (Bukar Sadong), Lara (Lara'). Studies have indicated that Serian is itself a subgroup consisting of various languages.
2. *Melanau subfamily*: Oya–Dalat, Mukah (Melanay), Matu Daro (Daro–Matu) and Rejang (Kayan, Rejang).
3. *Kayan subfamily*: Kayan languages of Baram (Kayan, Baram), Baluy, and Belaga.
4. *Kenyah subfamily*: Upper Baram Kenyah (Kenyah, Upper Baram) (Lepo Umbo', Lepo Tan, Lio Mato, Long Jaeh, and Long Tungan), and Lower Baram Kenyah (Merawan or Berawan, and Sebop).
5. *Kelabit subfamily*: Kelabit in Bario, Lun Bawang (Lundayeh) in Limbang, Tring, and Tabun.
6. *Penan subfamily*: Penan languages and subgroups in Mulu (the Penan Melinau), Upper Baram (Penan Busang), Sungai Tubu (Punan Tubu) (Penan Tubu), Sungai Terawang (Penan Libang), Long Iman (Penan Selungo), Belaga (Punan Bah–Biau) (Penan Ba), Niah (Penan La'ong and Penan Jelalong (Penan, Western)).
7. *Iban*: mainly in the Second, Sixth, and Seventh Divisions.
8. *Narom* in Marudu.
9. *Selakau* in Lundu.
10. *Bintulu* in Bintulu.
11. *Miri* in Miri.
12. *Baketan* (Bukitan), *Ukitan* (Ukit) *Lahanan*, *Kajang* and *Kejaman* (Kajaman), which are heterogenous languages of the Rejang area.

Sabah and Sarawak languages are minor languages, each with a few thousand speakers. Malay is the lingua franca among these groups. None has a writing system of its own.

Austroasiatic Languages

The speakers of these languages are the aborigines or the *orang asli*, who are found only in Peninsular Malaysia, around the Central Range stretching from Kedah in the north to Pahang and Selangor in the south. The languages may be divided into three groups: the Northern Group (Kensiu, Kentakbong, Jehai, Mendriq [Miriq], Bateg Deq [Batak], Mintil, Bateq Nong [Batek], Che Wong [Chewong]); the Central Group (Semnam, Sabum, Lanoh Jengjeng [Lanoh], Lanoh Yir, Temiar, Semai, Jak Hut); and the Southern Group (Mah Meri [Besisi], Semoq Beri [Semaq Beri], Semelai, Temoq). Semai has about 16 000 speakers and Temiar about 10 000. The others are well below these figures.

Temiar is the *lingua franca* among the aborigines.

The aboriginal groups of Jakun, Belandas, and Temuan are speakers of Malay in various dialectal forms.

Nonindigenous Languages

The nonindigenous languages can be divided into two groups: intraregional (whose speakers are from Indonesia and the Philippines) and extraregional (the Chinese dialects, the languages of the Indian subcontinent and Sri Lanka, Arabic, Thai, and English).

Languages from Indonesia and the Philippines

These languages are not widespread: Javanese in Selangor and Johor; Achehnese (Aceh) in Kedah; Mandailing (Batak Mandailing) in Perak and Selangor, Buginese (Bugis) and Chabacano (Chavacano) in Sabah.

There are also non-Malaysian dialects of Malay which had come to settle in parts of Malaysia: the

Rawa (Rawas), Kerinci, and Minangkabau dialects of Sumatra in Perak, Selangor, and Negeri Sembilan respectively; and Cocos (Malay, Cocos Islands) and Brunei Malay (Brunei) in Sabah.

Chinese Dialects

Chinese dialects in Malaysia are: Mandarin, Hokkien (Chinese, Min Nan), Hakka (Chinese, Hakka) (Khek), Cantonese (Chinese, Yue), Teochew & Hainanese (Chinese, Min Nan), Kwongsai, Hockchiu, Henghua (Chinese, Pur-xian), and Hockchua. Except for Mandarin, all the dialects have their own speech communities. The most populous is the Hokkien group, which has about 1 000 000 speakers, followed by Cantonese and Teochew. Mandarin is acquired through school education.

Languages of India and Sri Lanka

The languages of the Indian subcontinent and Sri Lanka altogether have just over 1 000 000 speakers. Of these, Tamil has the highest number of speakers (about 80% of the total Indian population). The other languages are Malayalam, Telugu, Gujarati, Sindhi, Bengali, Urdu, and Sinhalese (Sinhala).

Arabic

The speakers of Arabic as a first language do not form a community with its own geographical location. There seem to be more second-language speakers who have acquired Arabic through Islamic schools and colleges.

Thai

Thai is native to Malaysians of Thai origin living in the northern states of Perlis Kedah and Kelantan. It is a main requirement for police, customs, and immigration officers working along the northern border.

English

English has a very small first-speaker community of Eurasians, consisting of a few thousand people. It is an important language, besides Malay, in the professions such the legal and medical professions, the financial sector, trade, and business. It is also a language of academia.

Creoles and Pidgins

The two creoles in Malaysia are located in Melaka, in Peninsular Malaysia. The first is the Malay-based Baba Malay (Malay, Baba), spoken by the Babas, that is, descendants of the first group of 15th-century Chinese immigrants. The second is the Portuguese-based Kristang (Malaccan Creole Portuguese), spoken by the descendants of the Portuguese who ruled Melaka in the 16th and 17th centuries. Both creoles have a few thousand speakers.

A Malay pidgin, known as bazaar Malay, is used in the marketplaces. There are also pidgin Chinese and pidgin Tamil, which are intracommunity 'market languages.'

Maldives: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The Republic of Maldives consists of a chain of islands in the Indian Ocean, south of India and west of Sri Lanka, and has a population of about 335 000. The language of the Maldives is Dhivehi (Divehi), also known as Maldivian, an Indo-European language most closely related to Sinhala. The standard form of Dhivehi is based on the speech in the capital Male, while the forms of the southern atolls are the most divergent varieties. Dhivehi is also spoken by about 5000 speakers on Minicoy in India. Dhivehi is written in its own script called Tana (tāna, Thaana), written from right to left.

Dhivehi is the national language of the Maldives and is used in all spheres of society, including public administration and government, the media, and education. The vast majority of Maldivians are Muslims, but Arabic is not widely understood, and Dhivehi plays an important role for religious purposes and instruction. Dhivehi is used both in radio and television, as well as in print media. The literacy rate (2002) is 97.2%. English is used for international communication, and in the tourist

Rawa (Rawas), Kerinci, and Minangkabau dialects of Sumatra in Perak, Selangor, and Negeri Sembilan respectively; and Cocos (Malay, Cocos Islands) and Brunei Malay (Brunei) in Sabah.

Chinese Dialects

Chinese dialects in Malaysia are: Mandarin, Hokkien (Chinese, Min Nan), Hakka (Chinese, Hakka) (Khek), Cantonese (Chinese, Yue), Teochew & Hainanese (Chinese, Min Nan), Kwongsai, Hockchiu, Henghua (Chinese, Pur-xian), and Hockchua. Except for Mandarin, all the dialects have their own speech communities. The most populous is the Hokkien group, which has about 1 000 000 speakers, followed by Cantonese and Teochew. Mali: Language Situation

V Vydrine, Museum of Anthropology and Ethnography, St. Petersburg, Russia

© 2006 Elsevier Ltd. All rights reserved.

Mali is a large landlocked country of the West Africa of about 1.24 million sq. km in the mid–upper valley of Niger. More than a half of the country is a sparsely inhabited desert; the great majority of the population (10.5 million in 1998) is concentrated in the Niger valley and in the South.

Three major macrofamilies of Africa – Niger-Congo, Nilo-Saharan, and Afro-Asiatic – are represented in Mali. The Niger-Congo languages belong to four families: Mande (Bamana, Maninka, Kagoro, Marka-Dafing, Xasonka, Jalunga, Soninke, Bozo, Duun, Jo, Banka, Bobo), Atlantic (Pulaar/Fulfulde), Gur (the Senufo group, Bore, Pana, Samoma) and Dogon (Tommo-so, Toro-so, Jamsay, and others), altogether about 20 languages. Afro-Asiatic languages of Mali are Hassaniya (Mauritanian Arabic, the Semitic family) and the Tamasheq language/dialect cluster (the Berber family). Songhay languages form a linguistic family of their own; in fact, their belonging to the Nilo-Saharan macrofamily is largely contested by specialists (as is the coherence of that macrofamily itself). French is the official language of the country and the main language of the education; Arabic is the language of religion for the majority of the population of the country. In the mid-1990s a liberal law on Malian languages was adopted, and today a whole set of languages have status of 'national': Bamana, Pular/Fulfulde (Fula), Songhay (Gao), Tamasheq, Soninke, Xasonka, Maninka, Senufo, Minyanka, Boore, Dogon (Toro-so), Bozo (Tieyaxo).

Bamana (Bambara is its French name, borrowed from Soninke or Pulaar) is the most widespread language of the country. It is spoken as the first language by 26% of the population of Mali, and the entire number of the speakers amounts to an estimated 80%. Being the language of the capital, Bamako, it is often considered to be the 'Malian language.' The Bamako dialect serves the point of reference for the Standard Bamana, which is spoken in the main urban centers of Mali, its area has largely increased during the period following the independence of the country (1960). Today most of Senufo, Duun, Banka, Jo, and Bozo are bilingual in Bamana, as are a considerable part of Soninke, Fulbe, Dogon, Bobo, Xasonka. Lately, certain infiltration of the Bamana language is attested even in the Songhay area. In Mali the Maninka, whose language is closely related to Bamana (especially if it is the Maninka dialect of the Manding area that is meant), tend to identify themselves with Bamana. The same can be said about the Jula of the Sikasso area (in the South).

Rural Bamana dialects, spoken on both banks of the Niger from Bamako up to the Inner Delta, are rather different from the Bamako variant, often to a degree of mutual unintelligibility. The Bamana dialect of Segu is worth special mention: even after the eclipse of the Segu Empire (18th–19th centuries), it remains somewhat prestigious.

Maninka is in fact a dialect continuum of 800 000 to 900 000 speakers in the west of Mali. Its southeast variants (the Manding Maninka) are close enough to Bamana (for instance, they share a seven-vowel system), while the northwest variants (the Kenieba Maninka) are very close to the Xasonka and have a five-vowel system. The Kita Maninka is, in many respects, an intermediary variant. Kagoro is very close to the latter (about 15 000 speakers), it is spoken by dispersed groups in a great area to the north of Niger, from Kaarta to Segu. Many people

industry, which is an important part of the economy of the Maldives.

Mali: Language Situation

V Vydrine, Museum of Anthropology and Ethnography, St. Petersburg, Russia

© 2006 Elsevier Ltd. All rights reserved.

Mali is a large landlocked country of the West Africa of about 1.24 million sq. km in the mid–upper valley of Niger. More than a half of the country is a sparsely inhabited desert; the great majority of the population (10.5 million in 1998) is concentrated in the Niger valley and in the South.

Three major macrofamilies of Africa – Niger-Congo, Nilo-Saharan, and Afro-Asiatic – are represented in Mali. The Niger-Congo languages belong to four families: Mande (Bamana, Maninka, Kagoro, Marka-Dafing, Xasonka, Jalunga, Soninke, Bozo, Duun, Jo, Banka, Bobo), Atlantic (Pulaar/Fulfulde), Gur (the Senufo group, Bore, Pana, Samoma) and Dogon (Tommo-so, Toro-so, Jamsay, and others), altogether about 20 languages. Afro-Asiatic languages of Mali are Hassaniya (Mauritanian Arabic, the Semitic family) and the Tamasheq language/dialect cluster (the Berber family). Songhay languages form a linguistic family of their own; in fact, their belonging to the Nilo-Saharan macrofamily is largely contested by specialists (as is the coherence of that macrofamily itself). French is the official language of the country and the main language of the education; Arabic is the language of religion for the majority of the population of the country. In the mid-1990s a liberal law on Malian languages was adopted, and today a whole set of languages have status of 'national': Bamana, Pular/Fulfulde (Fula), Songhay (Gao), Tamasheq, Soninke, Xasonka, Maninka, Senufo, Minyanka, Boore, Dogon (Toro-so), Bozo (Tieyaxo).

Bamana (Bambara is its French name, borrowed from Soninke or Pulaar) is the most widespread language of the country. It is spoken as the first language by 26% of the population of Mali, and the entire number of the speakers amounts to an estimated 80%. Being the language of the capital, Bamako, it is often considered to be the 'Malian language.' The Bamako dialect serves the point of reference for the Standard Bamana, which is spoken in the main urban centers of Mali, its area has largely increased during the period following the independence of the country (1960). Today most of Senufo, Duun, Banka, Jo, and Bozo are bilingual in Bamana, as are a considerable part of Soninke, Fulbe, Dogon, Bobo, Xasonka. Lately, certain infiltration of the Bamana language is attested even in the Songhay area. In Mali the Maninka, whose language is closely related to Bamana (especially if it is the Maninka dialect of the Manding area that is meant), tend to identify themselves with Bamana. The same can be said about the Jula of the Sikasso area (in the South).

Rural Bamana dialects, spoken on both banks of the Niger from Bamako up to the Inner Delta, are rather different from the Bamako variant, often to a degree of mutual unintelligibility. The Bamana dialect of Segu is worth special mention: even after the eclipse of the Segu Empire (18th–19th centuries), it remains somewhat prestigious.

Maninka is in fact a dialect continuum of 800 000 to 900 000 speakers in the west of Mali. Its southeast variants (the Manding Maninka) are close enough to Bamana (for instance, they share a seven-vowel system), while the northwest variants (the Kenieba Maninka) are very close to the Xasonka and have a five-vowel system. The Kita Maninka is, in many respects, an intermediary variant. Kagoro is very close to the latter (about 15 000 speakers), it is spoken by dispersed groups in a great area to the north of Niger, from Kaarta to Segu. Many people

who identify themselves as Kagoro today speak only Bamana or Soninke.

Xasonka (about 130 000 speakers in the Kayes-Bafoulabe area, in northwest Mali) is very close to the adjacent variant of Maninka; it owes its status of a separate language to the strong ethnic identity of the Xasonka people, who trace their origin to a mixture of Fulbe, Maninka, and Soninke.

The dialects of the Marka-Dafing cluster (25 000 speakers in Mali) differ from Bamana and other predominant Manding languages by their 'inverse' tones and the presence of the segmental noun article *-o* (in Bamana, this article is represented by a floating low tone). Marka-Jalan, spoken in the town of San, is close the Marka-Dafin.

The Soninke (about 700 000 speakers) area is stretched from the west to the east along the Mauritanian border. Presumably the predominant language of the ancient Wagadu (Ghana) empire, it was much more widespread in the past, and numerous Soninke loanwords are attested in various languages of the western Sudan. Soninke diaspora is represented in all larger towns of Mali, and their villages can be found sometimes far away from the compact Soninke area.

The Bozo languages are spoken by traditionally fishermen population of about 120 000 in the middle flow of Niger and its tributaries. Four languages (sometimes referred to as dialects) are usually singled out: Xainyaxo (to the east of Segu), Tieyaxo (further to the east, especially around Diafarabe), Sorogaama, or Janama (Mopti and further to the north and west), and Tiema Cewe (in the northern part of the Inner Delta of Niger). Sorogaama, the largest of the Bozo languages, is internally diverse and has six different dialects. The Tieyaxo seems to be the most prestigious among the Bozo. In the west, the Bozo are mainly bilingual in Bozo and Bamana, and in the center and east, in Bozo and Fulfulde.

Only a minor number of Bobo speakers (15 000 to 20 000) live in Mali, to the south of the Boomu area; the others live in Burkina Faso. This language is characterized by a high degree of dialectal divergence, the dialects being not mutually intelligible; of these, Tinkire, Yebe, and Bana dialects are spoken in Mali. Most of the Bobo seem to be bilingual in Bamana or Jula. The position of the Bobo language within the Mande family is uncertain; it is sometimes singled out into a separate branch. On the other hand, it shares some common features and vocabulary with geographically close Samogo languages.

Duun (70 000 speakers), Jo (9100 in Mali and Burkina Faso), and Banka (5000) languages in the Sikasso area are also known as Samogo group (together with Dzuun, Kpan, and Seeku in Burkina Faso); the great majority of their speakers seems to be bilingual in Bamana. Traditionally included into the West Mande branch, they have much in common with the East Mande languages in vocabulary and morphology, including a complicated pronoun system and more than two tone levels. Jo is the only language in the Mande family that has the grammatical opposition of feminine vs. masculine in the pronoun system.

There are some Jalunga, or Jallonke (about 10 000 speakers) settlements in the Faleya area, at the Guinean border (near the Senegalese border). This Mande language is close to Soso on the Guinean coast. The Jallonke are descendants of the ancient population of the Futa-Jallon plateau (Guinea), ousted by Fulbe during the religious wars of the 18th century. Jalunga speakers in Mali are bilingual in Bamana, and their language seems to be endangered.

The only Atlantic language represented in Mali is Pulaar (this name is reserved for the western dialects), or Fulfulde (for the central and eastern dialects), the language of Fulbe, spoken by about 1 000 000 people in this country only. Traditionally nomads and livestock breeders, Fulbe are predominantly settled today, and their settlements are scattered all over Mali. There is a Fulbe family or two in most Bamana, Maninka, or Senufo villages taking care of the cows of the entire village. The largest compact area of Fulbe is Masiina (the Inner Delta of Niger), where the central dialects are spoken (more than 900 000 speakers). Some specialists consider these dialects to be the most archaic. Another compact zone is in the northwest of Mali, near the border with Mauritania and Senegal, where about 180 000 speak a Pulaar dialect that is close to the Senegalese ones. Being culturally diverse from the agricultural population, Fulbe have a strong sense of their identity and are often reluctant to use Bamana as lingua franca (that is also related to their attachment to Islam, which is much stronger than among the Bamana). Malian Fulbe represent just a segment of a their large diaspora stretching from Senegal to Sudan and even Ethiopia.

The most important Gur language spoken in Mali is Senufo, represented by several variants in the south of the country: Mamara, or Minyanka (500 000 to 900 000 speakers), Supyire (364 000), Syenara (137 000). These variants are divergent enough to be considered different languages. A great majority of Senufo are bilingual in Bamana, the language of the culturally dominant community.

Another big Gur language in Mali is Bore (Bomu, Bobo Wulen), spoken by about 100 000 people at the Burkina border. Two minor languages, Pana (Sama)

and Samoma (Kalamse), along the Burkina border, belong to the same family.

Dogon, earlier attached to the Gur family, is today considered to be a separate language family within Niger-Congo. The Dogon family numbers more than 20 languages (usually referred to as 'dialects of Dogon'), the most important ones being Jamsay, Toro-so, Tommo-so, Donno-so, and Togo-kan. The central languages and dialects are close to each other, while smaller peripheral languages are sometimes very different, to the extent that their belonging to the Dogon language family may be called into question. Of these languages, Toro-so has been given the status of 'standard Dogon,' a decision that is not yet generally approved. Many Dogon are bilingual in Bamana and in Fulfulde, but the latter often has negative connotations.

The Songhay family is represented in eastern Mali, mainly in the Niger valley, by Koyra Chiini (the Tombuktu Songhay, about 200 000 speakers), Koyraboro Senni (the Gao Songhay, about 400 000), Humburi Senni (about 15 000 in Mali), Tadaksahak (30 000 to 40 000, nomads culturally close to Tuaregs); there are also a couple of Zarma-speaking villages at the Niger border. The Songhay area demonstrates a staunch resistance to the penetration of Bamana as the lingua franca.

The Berber branch of the Afroasiatic family is represented in Mali by the languages of Tuaregs: Tamasheq (of which there are two considerably divergent dialects, Tombuktu and Tadhaq,with about 250 000 speakers) and Tamajaq (about 190 000 at the extreme east of Mali). After continuous wars against the central government in 1980–1990s, Tuaregs are being integrated into the Malian life (at least at the political level), but the penetration of Bamana in their milieu is still very slow.

Hasaniya, or Mauritanian Arabic, is spoken by about 100 000 people at the Mauritanian border.

The language of education at all levels is French; Arabic is taught in Koranic schools and madrasas. Education in the national languages (especially in Bamana, Fulfulde, and Songhay) is increasing both in schools and in adult literacy programs, but its quality often remains inferior. Nko writing is used for Bamana and Maninka to a certain extent, although Latin writing remains largely predominant. In Masiina, Adjami (arabographic writing) is still used by elders, but it is being overshadowed by Fulfulde writing on the basis of the Latin script. The same can be said about the Tefinag script among the Tuaregs.

Malinowski was born in Cracow, Poland. He was the son of a well-known Slavic philologist (Lucyan Malinowski). After a Ph.D. in physics and mathematics, he turned to anthropology, inspired, he said, by a reading of Frazer's *Golden bough*. In 1910 he arrived at the London School of Economics, and in 1914 began anthropological fieldwork in New Guinea. Between 1915 and 1918 he did two years of fieldwork on the Trobriand Islands (off Papua New Guinea). After some years teaching at the LSE he was appointed to the first Chair of Anthropology there (1927). In 1938 he went to the United States where he was appointed professor at Yale. He died in New Haven at the age of 58.

In the three great ethnographies of the Trobriand Islands (*Argonauts, Sexual life*, and *Coral gardens*), Malinowski established the tradition of intensive fieldwork, participating in the life of the society

and Samoma (Kalamse), along the Burkina border, belong to the same family.

Dogon, earlier attached to the Gur family, is today considered to be a separate language family within Niger-Congo. The Dogon family numbers more than 20 languages (usually referred to as 'dialects of Dogon'), the most important ones being Jamsay, Toro-so, Tommo-so, Donno-so, and Togo-kan. The central languages and dialects are close to each other, while smaller peripheral languages are sometimes very different, to the extent that their belonging to the Dogon language family may be called into question. Of these languages, Toro-so has been given the status of 'standard Dogon,' a decision that is not yet generally approved. Many Dogon are bilingual in Bamana and in Fulfulde, but the latter often has negative connotations.

The Songhay family is represented in eastern Mali, mainly in the Niger valley, by Koyra Chiini (the Tombuktu Songhay, about 200 000 speakers), Koyraboro Senni (the Gao Songhay, about 400 000), Humburi Senni (about 15 000 in Mali), Tadaksahak (30 000 to 40 000, nomads culturally close to Tuaregs); there are also a couple of Zarma-speaking villages at the Niger border. The Songhay area demonstrates a staunch resistance to the penetration of Bamana as the lingua franca.

The Berber branch of the Afroasiatic family is represented in Mali by the languages of Tuaregs: Tamasheq (of which there are two considerably divergent dialects, Tombuktu and Tadhaq,with about 250 000 speakers) and Tamajaq (about 190 000 at the extreme east of Mali). After continuous wars against the central government in 1980–1990s, Tuaregs are being integrated into the Malian life (at least at the political level), but the penetration of Bamana in their milieu is still very slow.

Hasaniya, or Mauritanian Arabic, is spoken by about 100 000 people at the Mauritanian border.

The language of education at all levels is French; Arabic is taught in Koranic schools and madrasas. Education in the national languages (especially in Bamana, Fulfulde, and Songhay) is increasing both in schools and in adult literacy programs, but its quality often remains inferior. Nko writing is used for Bamana and Maninka to a certain extent, although Latin writing remains largely predominant. In Masiina, Adjami (arabographic writing) is still used by elders, but it is being overshadowed by Fulfulde writing on the basis of the Latin script. The same can be said about the Tefinag script among the Tuaregs.

This article is reproduced from the previous edition, volume 5, pp. 2354–2355, © 1994 Elsevier Ltd.

Malinowski was born in Cracow, Poland. He was the son of a well-known Slavic philologist (Lucyan Malinowski). After a Ph.D. in physics and mathematics, he turned to anthropology, inspired, he said, by a reading of Frazer's *Golden bough*. In 1910 he arrived at the London School of Economics, and in 1914 began anthropological fieldwork in New Guinea. Between 1915 and 1918 he did two years of fieldwork on the Trobriand Islands (off Papua New Guinea). After some years teaching at the LSE he was appointed to the first Chair of Anthropology there (1927). In 1938 he went to the United States where he was appointed professor at Yale. He died in New Haven at the age of 58.

In the three great ethnographies of the Trobriand Islands (*Argonauts, Sexual life*, and *Coral gardens*), Malinowski established the tradition of intensive fieldwork, participating in the life of the society

being studied, emphasizing the effort to appreciate a total view of the society and to understand matters "from the natives' point of view." He constantly emphasized the importance of learning and working with the indigenous language. The vivid style of writing and the colossal amount of detail have established these ethnographies as classics. The account of the *kula* ring, a complex system of formal gift giving described in *Argonauts*, is one of the most celebrated cases in anthropology.

In terms of sociological theory, Malinowski's functionalism and his ideas about 'basic needs' are pretty banal, and are only of interest as indicating an important shift in anthropology away from questions about origins and evolution which had previously been so dominant. On the other hand, his concern with language is much more fruitful. He was proud of his ability to pick up languages quickly, and, as well as insisting on the importance of conducting field research in the native language, he shows an intense concern with the processes and details of translation (*Coral gardens*, vol. 2). He laments the lack of sound ethnolinguistic theory. Although his attempt to provide one does little with regard to phonetics, phonology, or grammar, his writing on meaning is original. In a remarkable essay (1923) appended to Ogden and Richards' *The meaning of meaning*, he coined the phrase 'phatic communion' (gossip, pleasantries, and so on) to make the point that language should not just be seen as a vehicle for thought through which to communicate ideas, but as a mode of action which, in this example, establishes personal bonds between people. Also in this essay he claims originality for the notion of 'context of situation' in an argument which prefigures Wittgenstein's 'the meaning of words lies in their use,' developed in *Philosophical investigations*.

J. R. Firth wrote: "I think it is a fair criticism to say that Malinowski's technical linguistic contribution consists of sporadic comments, immersed and perhaps lost in what is properly called his ethnographic analysis" (1957: 117). But beyond a strictly 'technical' contribution, his expertise in translating from Trobriand and his writing on meaning and translation deserve a more generous judgment.

Malkiel, Yakov (1914–1998)

S N Dworkin, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Born in Kiev, Malkiel received his doctorate from the Friedrich-Wilhelms Universität in Berlin in 1938, where he studied *Romanistik* under Ernst Gamillscheg. He left Germany in 1940 for the United States and joined the faculty of the University of California Berkeley in 1943, where he taught until his retirement in 1983.

Throughout his career, Malkiel was one of the leading and most prolific specialists in Romance historical linguistics. His most important work dealt with Spanish historical grammar, especially derivational morphology and etymology, the latter understood as the preparation of full-blown lexical biographies. Studies on the genesis and diffusion of a given derivational suffix were often flanked by inquiries into the history of etymologically obscure items that bear the suffix at issue. Malkiel was one of the few Romanists explicitly concerned with the theory and methodology of etymology. The need to rejuvenate Romance etymology by demonstrating how it could be integrated into ongoing research in other branches of diachronic research, especially phonology and morphology, is a constant theme in Malkiel's writings. His last book, *Etymology* (1993), is a personal overview and meditation on this field.

Malkiel also studied numerous problems in historical phonology and inflectional morphology, areas to which he made a number of significant

Malkiel, Yakov (1914–1998)

S N Dworkin, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Born in Kiev, Malkiel received his doctorate from the Friedrich-Wilhelms Universität in Berlin in 1938, where he studied *Romanistik* under Ernst Gamillscheg. He left Germany in 1940 for the United States and joined the faculty of the University of California Berkeley in 1943, where he taught until his retirement in 1983.

Throughout his career, Malkiel was one of the leading and most prolific specialists in Romance historical linguistics. His most important work dealt with Spanish historical grammar, especially derivational morphology and etymology, the latter understood as the preparation of full-blown lexical biographies. Studies on the genesis and diffusion of a given derivational suffix were often flanked by inquiries into the history of etymologically obscure items that bear the suffix at issue. Malkiel was one of the few Romanists explicitly concerned with the theory and methodology of etymology. The need to rejuvenate Romance etymology by demonstrating how it could be integrated into ongoing research in other branches of diachronic research, especially phonology and morphology, is a constant theme in Malkiel's writings. His last book, *Etymology* (1993), is a personal overview and meditation on this field.

Malkiel also studied numerous problems in historical phonology and inflectional morphology, areas to which he made a number of significant

methodological and analytical contributions. He advocated the concept of 'weak' sound change, i.e., a sound change that offered a relatively low degree of predictability. A key notion central to much of his diachronic research was multiple causation, the proposal that many linguistic shifts result from the interaction of several independent factors that come together to effect change. An explanatory hypothesis dear to his heart was the possible role of morphological conditions in sound change. Some sound changes may have taken as their starting point morphologically conditioned alternations, which then spread (often sporadically and unpredictably) beyond their original morphological locus. In his later years, Malkiel became fascinated by the possible role of phonosymbolism as a motivating and guiding factor in sound change. Phonosymbolism is to be understood here as the study of the intimate connection between the phonetic shape of a root morpheme and its meaning. The reader who wishes a sample of Malkiel's writings on this topic can turn to his *Edita and inedita, 1979–1988. Vol. I: diachronic problems in phonosymbolism*.

Although the overwhelming majority of his studies deal with specific issues in the history of Spanish and Portuguese, he also wrote on questions pertaining to the Romance languages as a whole, as well as on topics germane to Gallo-, Italo-, and Daco-Romance. His favorite medium for presenting the findings of his research was the monograph and the heavily documented article channeled through a learned journal or a homage volume. Starting around the mid–1960s, Malkiel placed more emphasis on the broader issues of linguistic change to be learned from the particular Romance problem under study. The symbiotic relationship between data-rich historical Romance linguistics and more theoretically oriented general linguistics is a major theme in his writings. Malkiel also wrote extensively on the history of Romance linguistics as a scholarly discipline. He was founding editor (1947) of the journal *Romance Philology*.

Collections of selected articles can be found in Malkiel (1968, 1979, 1989, 1990, 1992). An overview of his life and work can be found in Dworkin (1998, 2004).

Malmberg, Bertil (1913–1994)

B Sigurd, Lund, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Bertil Malmberg, professor of phonetics (1950–1969) and general linguistics (1969–1978) at the University of Lund, Sweden, was born on April 8, 1913 and died on October 8, 1994. He was an internationally well-known general linguist, phonologist, and Romanist, who also played a role in applied linguistics.

As a student, Malmberg encountered the structural movements in Europe, above all, the ideas of Ferdinand de Saussure and the Prague school with Nicolaj Trubetzkoj and Roman Jakobson. He spent several periods in Paris, where he learned experimental phonetics in the 1930s and was visiting professor of phonetics in the 1960s.

Malmberg was a pioneer in phonetics. He was quick to employ the sound spectrograph (Sonagraph) and managed to define the characteristics of the Swedish word accents manifested, e.g., in the famous minimal pair *ánden* ('the duck'): *ànden* ('the spirit'). He showed that the difference between accent one (acute) in *ánden* and accent two (grave) in *ànden* in the Southern Swedish dialect lies in the different placement of the intonation peak. Malmberg was also

methodological and analytical contributions. He advocated the concept of 'weak' sound change, i.e., a sound change that offered a relatively low degree of predictability. Malmberg, Bertil (1913–1994)

B Sigurd, Lund, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Bertil Malmberg, professor of phonetics (1950–1969) and general linguistics (1969–1978) at the University of Lund, Sweden, was born on April 8, 1913 and died on October 8, 1994. He was an internationally well-known general linguist, phonologist, and Romanist, who also played a role in applied linguistics.

As a student, Malmberg encountered the structural movements in Europe, above all, the ideas of Ferdinand de Saussure and the Prague school with Nicolaj Trubetzkoj and Roman Jakobson. He spent several periods in Paris, where he learned experimental phonetics in the 1930s and was visiting professor of phonetics in the 1960s.

Malmberg was a pioneer in phonetics. He was quick to employ the sound spectrograph (Sonagraph) and managed to define the characteristics of the Swedish word accents manifested, e.g., in the famous minimal pair *ánden* ('the duck'): *ànden* ('the spirit'). He showed that the difference between accent one (acute) in *ánden* and accent two (grave) in *ànden* in the Southern Swedish dialect lies in the different placement of the intonation peak. Malmberg was also

one of the first to use the equipment called Visible Speech at the Haskins laboratory in New York.

With his broad knowledge of the Romance languages, Malmberg had a wide field to which he could apply his ideas. He became a world famous Romanist, and his publications include works on and in French, Italian, and Spanish.

The sign plays a paramount role in Saussure's thinking, and Malmberg tried to include the theory of the linguistic sign under the general theory of signs (semiotics), as in *Le Langage—signe de l'human (1979)*. Malmberg often criticized the modern generative linguists for their lack of a sign concept. He did not take much interest in Chomsky and the generative school, which is also evident from his history of linguistics published in 1991, *Histoire de la linguistique: de Sumer à Saussure*.

The phonetics chair at Lund was partly motivated by the demands of language teaching, a field in which Malmberg was very active. He also started courses for speech therapists. Many of his books have been translated into several languages. The French version of his book on phonetics is a best-seller in the series *Que sais-je?*

Malta: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The republic of Malta is a group of islands in the central Mediterranean Sea, about 100 km south of Sicily. The three main islands are Malta, Gozo, and Comino. With about 400 000 inhabitants, the islands have a comparatively high population density. The main economic activities are shipping and port activities, finance, manufacturing, and tourism. Malta has been inhabited since prehistoric times and was an important port of the Phoenicians and Romans. The islands were under Arab control from 870 until the Norman Conquest in 1090. From the 16th century onward, the islands were the seat of the Knights of Malta, the monastic Order of St. John, who ruled the islands until the French invaded in 1798. In 1814, the islands became a British colony and only gained independence in 1964. Since 2004, Malta is a member of the European Union.

The two official languages of Malta are English and Maltese, a South Central Semitic language of Arabic origin. Maltese is in addition the national language. Besides Standard Maltese, there are also several dialects. Maltese is predominantly used in church services and other religious, national, and cultural activities. Until recently, much written official and administrative business was conducted in English, but increasingly efforts are being made to use Maltese. Maltese is used in courts, and the Maltese text is considered as legally binding.

Both Maltese and English are used in broadcasting and for the print media. However, most television is broadcast in English or received from Italian stations in Italian. There is no explicit policy regarding the use of languages in schools, but usually both Maltese and English are used, the former mostly in spoken communication and the latter for writing.

Most Maltese are bilingual in English and Maltese to a varying degree, and code-switching and-mixing between the two languages is common.

Malta: Language Situation

The republic of Malta is a group of islands in the central Mediterranean Sea, about 100 km south of Sicily. The three main islands are Malta, Gozo, and Comino. With about 400 000 inhabitants, the islands have a comparatively high population density. The main economic activities are shipping and port activities, finance, manufacturing, and tourism. Malta has been inhabited since prehistoric times and was an important port of the Phoenicians and Romans. The islands were under Arab control from 870 until the Norman Conquest in 1090. From the 16th century onward, the islands were the seat of the Knights of Malta, the monastic Order of St. John, who ruled the islands until the French invaded in 1798. In 1814, the islands became a British colony and only gained independence in 1964. Since 2004, Malta is a member of the European Union.

The two official languages of Malta are English and Maltese, a South Central Semitic language of Arabic origin. Maltese is in addition the national language. Besides Standard Maltese, there are also several dialects. Maltese is predominantly used in church services and other religious, national, and cultural activities. Until recently, much written official and administrative business was conducted in English, but increasingly efforts are being made to use Maltese. Maltese is used in courts, and the Maltese text is considered as legally binding.

Both Maltese and English are used in broadcasting and for the print media. However, most television is broadcast in English or received from Italian stations in Italian. There is no explicit policy regarding the use of languages in schools, but usually both Maltese and English are used, the former mostly in spoken communication and the latter for writing.

Most Maltese are bilingual in English and Maltese to a varying degree, and code-switching and-mixing between the two languages is common.

Maltese is the national language of the Republic of Malta and one of its two official languages, the other being English. It is spoken by virtually all the 345 418 (1985) inhabitants (plus ca. 80 000 Maltese immigrants in Australia). Until the 1930s, its status was low, with the prestige languages being Italian and English. The first text written in Maltese, a poem, is ca. 1460 AD, but although texts appear sporadically thereafter, Maltese only began to be written systematically from about the end of the eighteenth century.

Maltese, a language of Arabic origin, shares many of the features that distinguish the modern Arabic vernaculars from literary Arabic. Maltese also displays those features that distinguish Maghrebine dialects from the rest; for example, the loss of gender distinctions in second-person-singular pronouns and verbs and the leveling of first-person markers in the imperfect to give {n … ø} for the singular and {n … u} for the plural. However, Maltese differs from most 'core' vernaculars of Arabic by having (a) adopted the Roman alphabet; (b) a phonemic system without emphatics, with fewer back consonants but more vowels; (c) virtually the whole of the vocabulary pertaining to intellectual, technical, and scientific pursuits taken from Sicilian, Italian, and English; (d) a number of conservative lexical features (e.g., *ra* 'he saw'); and (e) grammatical innovations of Romance origin (e.g., passives with *kien* 'he was' or *ġie* 'he came' as auxiliaries). These features reflect the fact that Maltese has not had Classical Arabic as an acrolect for some seven centuries. This and the fact that it is now the national language of an independent state have given Maltese the status of a distinct language.

Malukan Languages

M Florey, Monash University, Clayton, VIC, Australia

© 2006 Elsevier Ltd. All rights reserved.

Some 128 languages are spoken in the geopolitical region of the Malukan islands in eastern Indonesia (see **Figure 1**). The majority of the 111 Austronesian languages of Maluku are subgrouped within the Central Malayo-Polynesian branch of Central-Eastern Malayo-Polynesian (CEMP) (Blust, 1978). A number of the Austronesian languages of north Maluku are subgrouped in the South Halmahera-West New Guinea branch of CEMP (Collins and Voorhoeve, 1983). Current information indicates that there are also 17 non-Austronesian languages spoken in Maluku (Grimes, 2000). Sixteen West Papuan phylum languages are found in the northernmost parts of Maluku, on Morotai, Ternate, Tidore, Halmahera, and nearby smaller islands. Oirata is a Trans-New Guinea phylum language of southern Kisar island, located near the north-eastern tip of East Timor.

Linguistically, Maluku is characterized by high linguistic diversity, serious endangerment, and little detailed documentation. Speaker populations have historically been much smaller than in ethnolinguistic communities in the western Austronesian region. Larger languages include Kei with 86 000 speakers and Buru with perhaps 43 000 speakers (Grimes, 1995). These numbers, however, give an overly optimistic picture of linguistic vitality. The highest documented degree of language endangerment in Indonesia is located in Maluku. A recent survey indicated that 10 languages are close to extinction and a further nine languages are seriously endangered (Florey, 2005). Centuries of contact with nonindigenous peoples through colonization and intensive trade for spices, and conversion to nonindigenous religions have all played a role in language endangerment, which is particularly severe in the central Malukan islands of Seram and Ambon. Language contact has resulted in the wide use of a number of Malay creoles throughout Maluku of which Ambonese Malay is the best known (Minde, 1997).

Malukan Languages

M Florey, Monash University, Clayton, VIC, Australia

© 2006 Elsevier Ltd. All rights reserved.

Some 128 languages are spoken in the geopolitical region of the Malukan islands in eastern Indonesia (see Figure 1). The majority of the 111 Austronesian languages of Maluku are subgrouped within the Central Malayo-Polynesian branch of Central-Eastern Malayo-Polynesian (CEMP) (Blust, 1978). A number of the Austronesian languages of north Maluku are subgrouped in the South Halmahera-West New Guinea branch of CEMP (Collins and Voorhoeve, 1983). Current information indicates that there are also 17 non-Austronesian languages spoken in Maluku (Grimes, 2000). Sixteen West Papuan phylum languages are found in the northernmost parts of Maluku, on Morotai, Ternate, Tidore, Halmahera, and nearby smaller islands. Oirata is a Trans-New Guinea phylum language of southern Kisar island, located near the north-eastern tip of East Timor.

Linguistically, Maluku is characterized by high linguistic diversity, serious endangerment, and little detailed documentation. Speaker populations have historically been much smaller than in ethnolinguistic communities in the western Austronesian region. Larger languages include Kei with 86 000 speakers and Buru with perhaps 43 000 speakers (Grimes, 1995). These numbers, however, give an overly optimistic picture of linguistic vitality. The highest documented degree of language endangerment in Indonesia is located in Maluku. A recent survey indicated that 10 languages are close to extinction and a further nine languages are seriously endangered (Florey, 2005). Centuries of contact with nonindigenous peoples through colonization and intensive trade for spices, and conversion to nonindigenous religions have all played a role in language endangerment, which is particularly severe in the central Malukan islands of Seram and Ambon. Language contact has resulted in the wide use of a number of Malay creoles throughout Maluku of which Ambonese Malay is the best known (Minde, 1997).

Figure 1 Map of Indonesia showing the location of the Malukan islands.

Tryon (1994: 12) suggested that Maluku is possibly the least known Austronesian area and many languages – both Austronesian and non-Austronesian – remain undescribed. The richest descriptions to date include those of Alune (Florey, 1998, 2001) and Buru (Grimes, 1991, 1995) in central Maluku, Taba (Bowden, 2001) and Tidore (Staden, 2000) in north Maluku, and Leti (Engelenhoven, 1995) in south Maluku. These descriptions provide some insights into oral genres, including origin tales, historical narratives, folktales, riddles, and incantations. Parallelism (paired correspondences at the semantic and syntactic levels) is a feature of incantations and some narrative genres. Among the special registers which have been documented are those which were associated with avoidance relationships, hunting, fishing, healing, and headhunting. In some communities, ritual language still accompanies ceremonies held to mark the passing of life stages, and ritual practices associated with agriculture, renewing inter-village alliances, and the building of ritual houses.

Comparative analysis indicates that, in central Malukan languages, the preferred word order within clauses is SVO. Actor arguments in Alune may occur as a full noun phrase, a pronoun, or a proclitic, and actor NPs and pronouns are optionally crossreferenced with a proclitic on the verb. Undergoer arguments may occur as a full noun phrase, a pronoun, or an enclitic.

Au beta-'u-ru
1SG opp.sex.sibling-1SG.POSS.INALIEN-PL

esi-tneu behe a-'eri-'e sarei
3PL-ask CMP 2SG-work-APP what
'my younger siblings they asked me: "What did you work at?"' (Alune AK: 45)

This pattern of crossreferencing is not always apparent today as the rapid language change which accompanies language endangerment is typically characterized by extensive variation both within and between speech communities.

A morphologically marked alienable–inalienable contrast has been described for a number of the languages of Central Maluku. Synchronically, this contrast is not found across all languages. In those languages in which the contrast is marked, inalienable possession denotes all items which are culturally considered to be intrinsically a part of oneself – the things which we as humans are born with, and certain physical and emotional states. Alienable possession denotes the things which we might acquire through our lives: certain relationships and objects or possessions. Inalienable possession is marked with enclitics and alienable possession with proclitics, as demonstrated in the following Haruku examples:

Au oi kura au ama-'u
1SG go with 1SG father-1SG.POSS.INALIEN
kura au ina-'u
and 1SG mother-1SG.POSS.INALIEN
'I went with my father and my mother'

Esi-kana esi-lapu-na
3PL-fetch 3PL.POSS.ALIEN-shirt-NM.PL
lalu ani reu
then.MAL 1PL return.home
'they fetched their shirts then we went home'

Mambila

B Connell, York University, Toronto, ON, Canada

© 2006 Elsevier Ltd. All rights reserved.

Mambila is a Bantoid language situated in the Nigeria-Cameroon borderland. Mambila is a diverse language with approximately 20 different dialects. Among its interesting characteristics is its system of four level tones, and in one lect the presence of two fricative vowels that appear to be reflexes of the so-called super-close vowels of Proto-Bantu. Several Mambila lects are endangered, with some on the verge of extinction.

Classification

Mambila has been recognized since the early 1960s as a Bantoid language. A subgrouping within Bantoid now known as Mambiloid, which includes a number of other languages in the region, was proposed a decade later, although the precise relationship between Mambiloid and the rest of Bantoid remains a matter of debate.

Mambila is the most diverse of the Mambiloid languages. It is spoken on both sides of the Nigeria-Cameroon border, on the Mambila Plateau in Nigeria, and on the western edges of the Adamawa Plateau and the Tikar Plain in Cameroon. The great majority of Mambila speakers – an estimated 90 000 of 100 000 total speakers – are in Nigeria. Mambila comprises some 20 dialects, which are divided into two clusters, referred to by their rough geographical orientation as East and West Mambila. Within each cluster there is limited mutual intelligibility among dialects, reflecting a dialect continuum; between the two clusters, mutual intelligibility does not exist, although speakers do recognize the relatedness of their languages to other languages in the region. Strictly on the basis of linguistic criteria, one might be inclined to refer to many of these dialects as distinct languages.

Mambila

B Connell, York University, Toronto, ON, Canada

© 2006 Elsevier Ltd. All rights reserved.

Mambila is a Bantoid language situated in the Nigeria-Cameroon borderland. Mambila is a diverse language with approximately 20 different dialects. Among its interesting characteristics is its system of four level tones, and in one lect the presence of two fricative vowels that appear to be reflexes of the so-called super-close vowels of Proto-Bantu. Several Mambila lects are endangered, with some on the verge of extinction.

Classification

Mambila has been recognized since the early 1960s as a Bantoid language. A subgrouping within Bantoid now known as Mambiloid, which includes a number of other languages in the region, was proposed a decade later, although the precise relationship between Mambiloid and the rest of Bantoid remains a matter of debate.

Mambila is the most diverse of the Mambiloid languages. It is spoken on both sides of the Nigeria-Cameroon border, on the Mambila Plateau in Nigeria, and on the western edges of the Adamawa Plateau and the Tikar Plain in Cameroon. The great majority of Mambila speakers – an estimated 90 000 of 100 000 total speakers – are in Nigeria. Mambila comprises some 20 dialects, which are divided into two clusters, referred to by their rough geographical orientation as East and West Mambila. Within each cluster there is limited mutual intelligibility among dialects, reflecting a dialect continuum; between the two clusters, mutual intelligibility does not exist, although speakers do recognize the relatedness of their languages to other languages in the region. Strictly on the basis of linguistic criteria, one might be inclined to refer to many of these dialects as distinct languages.

For this reason, the neutral term 'lect' is used in referring to individual varieties of Mambila.

The main characteristic distinguishing the two dialect clusters is a difference in morpheme structure: In East Mambila a disyllabic root structure, CVCV(C), predominates, which corresponds to a monosyllabic CVC structure in West Mambila. A number of sound correspondences also serve to distinguish the two groupings, e.g., initial /f/ and /h/ in East Mambila correspond to /p/ and /f/, respectively, in West Mambila.

Little descriptive work has been done on Mambila. The two lects that have received the greatest attention are Tungba, spoken in Nigeria, and Ba, in Cameroon. Both are West Mambila lects. The following paragraphs present a short summary of Mambila structural characteristics.

Phonology

Consonants

Across Mambila lects there is little difference among consonant systems; what differences do exist are mostly related to the historical developments described above. The Ba system, /p, b, t, d, k, g, k͡p, g͡b, m, n, ɲ, ŋ, ŋ͡m, mb, mv, nd, ndʒ, ŋg, ŋ͡mg͡b, f, v, s, h, l, j, w/, is fairly typical, both in its inventory and in the fact that /p, k͡p, g͡b, and ŋ͡mg͡b/ in those lects, where they do occur, are infrequent. Distribution of consonants within the word is skewed in Mambila, with all consonants occurring in the initial position, but typically only /p, t, k, m, n, ɲ, ŋ, l/ being found word finally.

Vowels

There is greater variation in the vowel systems of Mambila lects than for the consonants. The vowel system found in Ba, /i, e, a, ə, u, o, ɔ/ is the smallest; Tungba has only a slightly larger system, /i, e, ɛ, a, u, o, ɔ, ɑ/, but its phonetic realization is divergent, with allophonic front rounded vowels. Len, another West Mambila lect, is even more divergent, particularly with the presence of two fricative vowels, /z͡ɨ, ʊ͡ɯ/. These vowels appear to be the result of sub- or adstratal influence from the neighboring Grassfields languages, which may ultimately reflect the super-close vowels of Proto-Bantu.

Tone

Mambila is a register tone language; in West Mambila, it features four level tones that function both lexically and grammatically, and tones combine on single syllables to form a number of surface contours. Pitch realization in the Ba lect has been the subject of a number of experimental phonetic studies (Connell, 1999, 2000b, 2002). Tone in East Mambila lects has not been systematically investigated, although it is known that they have only three level tones.

Morphology

Mambila marks grammatical functions through affixation, typically suffixation. In most West Mambila dialects many of these functions are indicated only with a tonal morpheme; comparative evidence from both West and East Mambila reveals that a −CV melody is reconstructible in most cases. Despite the fact that Mambila is a Bantoid language, there is no system of nominal classification, and only traces remain of a former noun class system that reveals the heritage shared with Bantu. Pluralization is marked through means of a segmental suffix, −bV, except in Ba and other lects on the Tikar Plain, where a cognate prefix is used. There is evidence of an older means of marking plurals, and the presence of the common −bV is likely a recent development, perhaps through areal influences.

Syntax

Little can be said at this point concerning the syntax of Mambila. It has basic SVO word order, which varies to indicate narrative, focus, and other pragmatic functions. As mentioned above, tone is used to indicate a number of grammatical functions, including negation, imperatives, and discontinuous verb phrases.

Language Vitality

Since it has more than 100 000 speakers, one might expect that Mambila will remain relatively stable for the foreseeable future. However, when its internal dialect variation is considered, an average of approximately 5000 speakers exists for each lect. Many of these are spoken by considerably fewer speakers; indeed, a few Mambila lects are on the verge of extinction, while one other has just recently become extinct. Given the potential contribution that these lects could make not only to our understanding of our common linguistic heritage but also to the history and prehistory of sub-Saharan Africa, documentation of these lects must be considered a priority.

Manambu

A Y Aikhenvald and P Y L Laki, La Trobe University, Bundoora, Australia

© 2006 Elsevier Ltd. All rights reserved.

Manambu belongs to the Ndu language family, and is spoken by about 2500 people in five villages: Avatip, Yawabak, Malu, Apa:n and Yuanab (Yambon) in East Sepik Province of Papua New Guinea. Between 200 and 400 speakers live in the towns of Port Moresby, Wewak, Lae, and Madang. Most Manambu speakers are proficient in Tok Pisin, the *lingua franca* of Papua New Guinea; many know English. In terms of number of speakers, the Ndu family is the largest in the Sepik area, comprising 32% of the Sepik basin dwellers (Roscoe, 1994). It consists of at least eight languages spoken by over 100 000 people along the course of the middle Sepik River and to the north of it. Other documented languages in the family are: Abelam or Ambulas (ca. 40 000; this number includes speakers of a variety of dialects under the names of Maprik, Wosera, West Wosera, and Hanga Kundi); Boikin (ca. 30 000); Iatmul (ca. 12 000); Sawos (ca. 9000); Yelogu (ca. 200); and Ngala (ca. 130). No genetic links between Ndu and other languages of the Sepik area have been proved. The origins, protohome, and the internal classification of the Ndu languages remains a matter for debate. Manambu's closest relatives are Iatmul and Ngala. The trade relationship and marriage exchange with the Iatmul contributed to a large amount of lexical diffusion between the two groups in close contact.

Manambu is synthetic, agglutinating with some fusion, mostly suffixing, and predominantly verb-final. The phonology of Manambu is complicated, with 21 consonants, nine vowels, and contrastive stress. Nouns distinguish eight cases (subject, definite object/locative; dative/aversive; allative/instrumental; comitative; terminative 'up to the point'; and two cases referring to 'means of transport'). Three numbers (singular, dual, and plural) and two genders (feminine and masculine in the singular) are expressed via agreement on demonstratives, interrogatives, in possessive constructions, on verbs and on two adjectives ('big' and 'small'). Singular and plural numbers are marked on kinship nouns, and on a few nouns from other semantic groups. The noun 'child' has a semisuppletive form for the dual number. Associative plural is marked on kinship nouns and personal names, as in *Tanina-b*ˌ*r* 'Tanina and others.' Gender is distinguished in second and third person singular independent pronouns, and neutralized in the plural. Nouns are assigned genders according to the sex of a human referent, and to shape and size of any other referent. That is, men are assigned to the masculine, and women to the feminine gender; a large house is masculine, and a small house feminine. By semantic extension, an unusually big or bossy woman can be treated as masculine, and a squat fattish man as feminine. Personal names are a distinct subclass of nouns, with special derivational suffixes not used anywhere else in the grammar.

Verbs have a plethora of grammatical categories, covering person, number, gender, tense, numerous aspects (e.g., completive, habitual, and repetitive) and modalities including irrealis, purposive, desiderative, and conditional. A verb in the declarative mood can cross-reference the person, number, and gender of the subject. Or, if a clause contains a constituent that is more topical than the subject, this constituent can also be cross-referenced alongside the subject. The

Manambu

A Y Aikhenvald and P Y L Laki, La Trobe University, Bundoora, Australia

© 2006 Elsevier Ltd. All rights reserved.

Manambu belongs to the Ndu language family, and is spoken by about 2500 people in five villages: Avatip, Yawabak, Malu, Apa:n and Yuanab (Yambon) in East Sepik Province of Papua New Guinea. Between 200 and 400 speakers live in the towns of Port Moresby, Wewak, Lae, and Madang. Most Manambu speakers are proficient in Tok Pisin, the *lingua franca* of Papua New Guinea; many know English. In terms of number of speakers, the Ndu family is the largest in the Sepik area, comprising 32% of the Sepik basin dwellers (Roscoe, 1994). It consists of at least eight languages spoken by over 100 000 people along the course of the middle Sepik River and to the north of it. Other documented languages in the family are: Abelam or Ambulas (ca. 40 000; this number includes speakers of a variety of dialects under the names of Maprik, Wosera, West Wosera, and Hanga Kundi); Boikin (ca. 30 000); Iatmul (ca. 12 000); Sawos (ca. 9000); Yelogu (ca. 200); and Ngala (ca. 130). No genetic links between Ndu and other languages of the Sepik area have been proved. The origins, protohome, and the internal classification of the Ndu languages remains a matter for debate. Manambu's closest relatives are Iatmul and Ngala. The trade relationship and marriage exchange with the Iatmul contributed to a large amount of lexical diffusion between the two groups in close contact.

Manambu is synthetic, agglutinating with some fusion, mostly suffixing, and predominantly verb-final. The phonology of Manambu is complicated, with 21 consonants, nine vowels, and contrastive stress. Nouns distinguish eight cases (subject, definite object/locative; dative/aversive; allative/instrumental; comitative; terminative 'up to the point'; and two cases referring to 'means of transport'). Three numbers (singular, dual, and plural) and two genders (feminine and masculine in the singular) are expressed via agreement on demonstratives, interrogatives, in possessive constructions, on verbs and on two adjectives ('big' and 'small'). Singular and plural numbers are marked on kinship nouns, and on a few nouns from other semantic groups. The noun 'child' has a semisuppletive form for the dual number. Associative plural is marked on kinship nouns and personal names, as in *Tanina-b*ˌ*r* 'Tanina and others.' Gender is distinguished in second and third person singular independent pronouns, and neutralized in the plural. Nouns are assigned genders according to the sex of a human referent, and to shape and size of any other referent. That is, men are assigned to the masculine, and women to the feminine gender; a large house is masculine, and a small house feminine. By semantic extension, an unusually big or bossy woman can be treated as masculine, and a squat fattish man as feminine. Personal names are a distinct subclass of nouns, with special derivational suffixes not used anywhere else in the grammar.

Verbs have a plethora of grammatical categories, covering person, number, gender, tense, numerous aspects (e.g., completive, habitual, and repetitive) and modalities including irrealis, purposive, desiderative, and conditional. A verb in the declarative mood can cross-reference the person, number, and gender of the subject. Or, if a clause contains a constituent that is more topical than the subject, this constituent can also be cross-referenced alongside the subject. The

imperative mood also marks person and number of the subject employing a different set of markers. The only fully productive prefix in the language is *a-*, the marker of second person imperative. Three suffixes expressing prohibition differ in their illocutionary force. Many of the verbal categories – including person and tense – are neutralized in negative clauses. Verb compounding is highly productive; up to three verbal roots can occur together, but the meaning of the combination is frequently unpredictable. Directionality (up, down, inside, outside) is marked both on verbs and on demonstratives. In addition, demonstratives encode six degrees of distance and visibility.

Similarly to other non-Austronesian languages of New Guinea, Manambu has extensive clause-chaining and a complex system of switch-reference, whereby a nonfinal clause is marked differently depending on whether its subject is the same, or differs, from that of the main clause. See Aikhenvald with Laki (forthcoming) for a full account of Manambu grammar, and also Aikhenvald (1998) and Allen and Hurd (1972). The relative complexity of Manambu could be partially accounted for by the substrata of languages spoken by members of neighboring tribes conquered by the Manambu as a result of inter-tribal warfare (Harrison, 1993).

Manambu culture places particular importance on ownership of personal names and various kinds of cultural knowledge. Ritualized debates among rival leaders and the clan groups they represent are, traditionally, the main political forum, and ownership of names is an oft-debated issue. A detailed study of Manambu ethnography is in Harrison (1990, 1993), which also contains a detailed analysis of the kinship system and relationships (of Siouan type). Traditional genres include mourning songs *grakudi* and foiled marriage songs *namai* (Harrison, 1982; Takendu, 1977).

Manambu is an endangered language. All the Manambu are bilingual in Tok Pisin (and some also know English). Children in the villages prefer using the local *lingua franca*, Tok Pisin, in their day-to-day interaction. A literacy program in Manambu is currently being implemented at the local school at Avatip.

Mande Languages

D Dwyer, Michigan State University, East Lansing, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

The Distribution of the Mande-Speaking People

Today, the Mande (or *Mandé* in French) language group consists of some 30 languages spoken in West Africa from Nigeria to Senegal by an estimated 10 million speakers. The term Mande and its variants (see Table 1) provide not only the basis for many of the names of the Northern Mande languages, but the various names accorded the language family as well. These variants are attributable to (1) minor vowel alternations (*e/i* and *a/e*), (2) the consonantal alternation (*nd/n/l*) found throughout the Mande-speaking area, and (3) the suffix *-ka(n)*, meaning 'language or dialect.'

The map of the distribution of the Mande languages (Figure 1) shows that the heaviest concentration of Mande languages is in the republics of Guinea and Mali, and adjacent areas of Senegal, Sierra Leone, Liberia, and Ivory Coast. Furthermore, these western languages are contiguous and cover larger areas than those to the east, which appear as islands in a sea of Niger-Congo languages.

The Reconstructed History of the Mande

While scholars have not reached a total consensus on how the Mande evolved, evidence from the historical, archaeological, and linguistic record suggests the following six stages.

Phase 1: The Drying of the Desert

According to McIntosh and McIntosh (1984), the Mande originally lived in a much wetter Saharan area and practiced a herding–fishing–collecting economy. Lexicostatistical evidence (Dwyer, 1989) suggests that 4000 years ago the Mande people were undifferentiated linguistically.

Around 3000 B.P. (before present), in response to the increasing lack of rainfall, one branch of Proto-Mande (the earliest form of Mande) speakers migrated southward where wetter conditions would permit their herding–fishing–collecting way of life. The other branch, known as the western branch, responded to the increasing dryness by intensifying their cultivation of cereals.

Phase 2: The Development of Agriculture

At Jenno-Jene in the upper Niger delta, archaeologists have identified a site, continuously occupied from about 2250 B.P., that exhibits a second agricultural phase. This elaboration of agriculture may well have been responsible for the diversification and the westward expansion of the Central Mande speakers. This expansion may also have been responsible for pushing the pastoral Soninke further to the north.

Phase 3: The Rise of the Sudanic Kingdoms of Ghana and Mali

At the time of the sedentarization of the Western Mande, the people of this area were engaged in extensive trans-Saharan trade with North Africa. The stimulus for the trade was the alluvial gold found in deposits along the upper Niger River, which was exchanged for Mediterranean merchandise and salt. This trade gave rise to the Soninke-speaking empires of Ghana (700–1100) and the Manding-speaking empire of Mali (800–1550) The substantial area taken up by the Western Mande can be attributed to the expansion of this empire.

Phase 4: Rice and the Development of Forest Agriculture

While research in this area is still in progress, evidence suggests that a form of upland rice in the Guinea Highlands and iron tools permitted the Mande (and Atlantic) populations living along the rainforest–savannah border to enter the forest to practice swidden agriculture. The map shows a number of Mande groups straddling this line including the Southwestern Mande, the Vai/Kono into present-day Sierra Leone and Liberia, and many of the Eastern Mande peoples into Liberia and Ivory Coast. Using oral traditions and genealogies, Person (1961) concludes that this movement into the rain forest took place in the 15th century. As these agricultural people moved into the sparsely populated rain forests, they increased the risk of malarial infections. In response to this situation, the percentages of the sickle cell trait (an adaptation to malaria) increased in these populations to the point where they are among the highest in the world (Livingstone, 1958).

Western	wine, mortar, pestle dog, oil?, chicken? hippo?, to plant?, seed?	Eastern Mande
2400 BP		
Northern Southwestern	iron, hoe, to plant corn/millet, chicken oil, seed	

Phase 5: The Arrival of the Europeans

Beginning with the Portuguese in 1455, contacts, trade, and finally settlement in this area increased, so that by 1500 permanent trading outposts and slaving operations were fully established. One effect of this development was the decreasing economic importance of the trans-Saharan trade and the decline of the Sudanic kingdoms.

The Linguistic Evidence

Following a technique developed by Ehret (1980), Table 2 shows the Proto-Mande terminology relating to economic activity (hunting, herding, and agriculture). After establishing the lexicostatistical dates, vocabulary common to all or most members of the branch are considered to be in existence at the time the branch was an undifferentiated language. Thus the terms for wine, mortar, and dog were common to the western branch but not the eastern branch, and are presumed to have been part of Western Mande before it separated into its constituent groups. This linguistic evidence is consistent with that proposed for the early phases of Mande.

The Classification of Mande Languages

Current Classification

The internal classification of Mande (see Table 3) has undergone a series of revisions, the most recent and most accurate being that done by Kastenholtz (1996). For a full classification of the Mande languages go to the Ethnologue website.

Earlier Classifications

Mande was first recognized as a related group of languages by Sigmund Koelle, who used the term Mandinga (Koelle, 1854). Shortly thereafter Heymann Steinthal (1867) introduced the term Mande (or *Mandé*). Maurice Delafosse offered the first subclassification of Mande in 1901, in which the major distinction was between Mande Tan (which is the northern group minus Susu and Yalunka) and Mande Fou, based on the words for 'ten.' Over time, the Tan/Fou categorization became increasingly suspect, but it was not until William Welmers (1958), using a lexicostatistical approach based on the Swaddesh 100-word basic vocabulary list, rejected it and produced the first version of the currently accepted system. Welmers concluded that the word *tan* was a

Table 3 Current classification

Mande 4000 BP[a]			
West Mande 3200 BP		*Eastern Mande 2400 BP*	
Central (southwestern) 3200 BP	*Northwestern 2400 BP*	*Eastern-eastern*	*Eastern southern*
South western 3000 BP	Jowulu	Bisa (Bissa)	Guro-Tura
Kpelle	Soninke-Bobo 2750 BP	Barka	Guro
Mende Looma (Loma)	Bobo	Lebir	Yaouré
Central 2100 BP	Soninke	Busa	Tura (Toura)
Susu-Yalunka		Boka (Boko)	Dan
Manding-Jogo		Bokabaru (Bokobaru)	Mano
		Busa-Bisa (Busa)	Nwa-Ben
		Tyenga (Kyenga)	Ben
		Sam (Samo)	Gban (Gogu)
		San (Samo)	Nwa (Wan)
		Sane (Samo)	Mwan

[a]The BP dates are from Dwyer (1989). Each date represents the estimated date at which the languages in the group separated, based on common percentages of basic vocabulary cognates. Thus Central Mande, for example, with its time depth of 2100 BP, is based on a common cognate percentage of 40%.

more recent innovation in Western Mande, not the fundamental split that Delafosse had assumed, and introduced the East–West division that remains today.

Mande as a Niger-Congo Language

Since the time of Koelle, four major hypotheses concerning the placement of Mande in Niger-Congo have been offered:

- Westermann (1927) included Mande in his West Sudanic, which was very similar to Greenberg's Niger-Congo (Table 4).
- In 1963, Joseph Greenberg, using a methodology based on the mass comparison of lexical items, accepted and refined Westermann's view. He renamed West Sudanic as Niger-Congo, the name it bears now, and included it as a branch of a larger grouping, Niger-Kordofanian. Of all the Niger-Congo languages, Greenberg considered Mande the least remote (Table 5).
- Consistent with common usage, Williamson (1977) replaced Greenberg's Niger-Kordofanian with the term Niger-Congo. Williamson then placed Mande along with Atlantic Congo (the main body of Niger-Congo languages) and Kordofanian as the first three branches of Niger-Congo (Table 6).
- Also in 1977, Hans Mukarovsky proposed a substantial restructuring in which Mande and

Table 7 Mukarovsky

Benue-Congo were removed from the old Niger-Congo (renamed West Sahelian) and placed with Songhai (Songhay), previously not considered a Niger-Congo language, as branches of Sahelian (Table 7).

Although the Mukarovsky model is still seen as an interesting hypothesis, currently most scholars favor the Williamson proposal. Nevertheless, the progression from Westermann to Williamson to Mukarovsky does show an increasing awareness of Mande as a remote branch of Niger-Congo. This development has raised questions about whether Mande is actually a Niger-Congo language. Part of this suspicion is due to the fact that Mande is also unique among the Niger-Congo languages because of its lack of evidence of a noun class system, found in other Niger-Congo languages, and its almost universal subject-object-verb word order.

This led Dwyer (1998) to compare the vocabulary of Mande and samples from other Niger-Congo branches. This study shows that Mande is a lexically coherent group. By lexically coherent, I mean that the best way to explain the vocabulary basic and other is to attribute a common ancestor (Proto-Mande) to these languages. The study also found that Niger-Congo (specifically Mande, Benue-Congo (including Bantu) and the western Nigritic core) is also lexically coherent. Finally, the study concluded that of these three language groups, Mande is lexically least related. These conclusions are fully consistent with the Williamson hypothesis but not that of Mukarovsky.

Linguistic Properties

Phonology

A tentative reconstruction of the Proto-Mande consonant system (Table 8) suggests a series of labial, alveolar, velar, and labiovelar voiced and voiceless stops. Because of the eccentric, but relatively consistent bimodal patterning of the voiceless stops, Dwyer (1994) tentatively suggested the possibility of a second series of fortis voiceless stops (*t′*, *k′*, *kp′*). Interestingly, this dual series of voiceless stops is analogous to that postulated for Upper Cross by Dimmendaal (1978) and Sterk (1979) and for Volta-Congo, Stewart (1976). In addition Mande appears to have only an (*s/z*) fricative contrast and labial, alveolar, and palatal nasals along with the liquid (*l*) and the glides (*y* and *w*).

Tone

Most Mande languages have two level lexical tones (high and low), along with a falling tone, analyzed as a sequence of high followed by low, and a rising tone. Bobo (Bobo Madaré), Mano, and Kpelle have three tones and one language, Sembla (Seeku), has four. Both Kpelle and Bobo (Bobo Madaré) (Dwyer, 1994) can be shown to have independently evolved a third tone through tone splitting. This suggests that they originally had a two-tone system.

Morphosyntax

One of the most striking facts about the Mande languages is the structural unity of the group and its distinctiveness from other Niger-Congo languages. Syntactically, the Mande languages have an SOV word order with oblique objects being marked as the objects of specialized postpositions. None of the Mande languages use serial verbs. Many Mande languages distinguish between alienable and inalienable possession.

Tense and aspect are generally marked through a combination of verb suffixes and postsubject formatives. Definite articles, demonstratives, and plurals tend to follow the noun or noun + attribute while possessive pronouns precede the noun.

Research in the area of comparative morphology and syntax is beginning to emerge. Creissels (1980) charted the distribution of four verbal particles in his Mandekan dialects with the conclusion that from

Table 8 Mande consonants

	Labial	*Dental*	*Palatal*	*Velar*	*Labiovelar*
Stop	p/b	t/d		k/g	kp/gb
Fricative		s/z			
Nasal	m	n	ñ		
Liquid/Glide		1	y		w

these data no clear evolutionary sequence could be ascertained. Grégoire (1980) compared the rather unique properties of Mande relative clauses from all of its major branches: northern, southwestern, southeastern, and Bobo. Dwyer (1985) has traced the evolution of the definite articles in Northwestern Mande.

Comparative reconstruction is a far more challenging task than lexicostatistical analysis, but promises more interesting results, not only in the study of the development of the language, but also in the area of cultural history and in understanding the relationship between synchronic and diachronic rules.

Noun Classes

Typically, Niger-Congo languages have several semantically based noun classes (animate, inanimate, diminutive, augmentative, and abstract), usually marked by prefixes, both singular and plural. Languages of the Mande branch do not make use of this morphological device. One possible explanation is that the noun class system developed after Mande separated from Niger-Congo. Alternatively the system could have been part of Niger-Congo and subsequently lost in Mande. In the latter situation, one would expect some evidence in some of the Mande languages of remnants of such a noun class system. However, despite numerous attempts no evidence has turned up. For example, Dwyer (1990) examined Bobo (Bobo Madaré), which has a very complex system of plural formation requiring the positing of a number of noun classes in order to derive the correct form. However, these noun classes did not turn out to be related (semantically or morphologically) to the Niger-Congo noun classes.

A number of Mande languages have developed writing systems, including a Vai syllabary (Stewart, 1972) that has been in use continuously since the 1830s.

Resources

The Mande Studies Association (MANSA) website has several useful links to other resources in French (*Actualités de la recherche au Mali* and the *Bulletin d'Anthropologie et d'Histoire Africaines en Langue Française*) and English. Both the Summer Institute of Linguistics and Ethnologue contain descriptions of individual Mande languages and more detailed maps. The site of the Union Mandingue has posted a history of the Manding-speaking peoples. Additional sources can by found by entering the individual language names given in this article in any search engine. The most thorough bibliography can be found in Kastenholz (1988).

Maori

W Bauer, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Maori is the language of the Polynesian people who settled in New Zealand over 1000 years ago. It belongs to the Eastern Polynesian branch of the Malayo-Polynesian language family. Its current situation is typical of indigenous languages subjected to the effects of European colonization.

The early English missionaries Samuel Marsden and Thomas Kendall were instrumental in having a writing system devised for Maori. This has largely served the language well, although it failed to distinguish between long and short vowels. The dictionary produced by three generations of the Williams family remains highly significant, and W. L. Williams made a substantial contribution to the grammatical description of Maori.

In the first half of the 20th century Maori children were taught English at the expense of Maori. Influential Maori leaders advocated the use of English in Maori homes, and speaking Maori at school was often punished. By the mid-20th century Maori was rapidly dying, although small Maori-speaking communities remained in isolated rural areas. In 1951, Auckland University introduced Maori as an academic subject, which raised its status a little as did the grammatical descriptions produced by the linguist Bruce Briggs. However, the future looked bleak.

In the 1970s, a Maori political revival began (the 'Maori renaissance'). It was accompanied by serious endeavors to revitalize the language. *Kohanga reo* 'language nests' were established (preschool education centers providing education in Maori), and these were followed by Maori medium schools (*kura kaupapa Māori*), or immersion or bilingual units in mainstream schools. Small Maori radio stations were established with variable amounts of broadcasting in Maori. The Maori language became an official language of New Zealand. A Maori Language Commission was established to aid revitalization, and it has manufactured many vocabulary items from Maori elements to cater to modern needs. A Maori television channel went on the air in 2004.

Today the future of Maori is unclear. It might survive, testimony to the success of the revitalization process, but it is not yet secure. Most speakers have learned Maori as a second language, and many are 'semi-speakers.' Many teachers of Maori are not fully fluent, and the quality of the Maori taught in some Maori-medium classrooms is poor. Many children who leave *kohanga reo* speaking fluently do not use the language as teenagers. Most native speakers of Maori are over 70 years old, although there are some (particularly from the Tuhoe area, where Maori remained strong 20 years longer than elsewhere) still in the workforce. It is common to hear 'relexicalized English' – English structures where the content words and some of the grammatical words are replaced by Maori lexical items. Fluent Maori speakers often speak English to each other rather than Maori. While the latest surveys suggest that more people are speaking more Maori, there are very few who are fully conversant with the language. The last New Zealand census contained a question about use of Maori.

Such dialect differences as exist are tribally based. Most are lexical and phonological (with divergent realizations of phonemes rather than different phonological systems), and grammatical differences are not very significant.

Maori has a small phoneme inventory, with ten consonants (/p t k m ŋ r w f h/), and five vowels (/a e i o u/), each of which may be short or long.

Maori

W Bauer, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Maori is the language of the Polynesian people who settled in New Zealand over 1000 years ago. It belongs to the Eastern Polynesian branch of the Malayo-Polynesian language family. Its current situation is typical of indigenous languages subjected to the effects of European colonization.

The early English missionaries Samuel Marsden and Thomas Kendall were instrumental in having a writing system devised for Maori. This has largely served the language well, although it failed to distinguish between long and short vowels. The dictionary produced by three generations of the Williams family remains highly significant, and W. L. Williams made a substantial contribution to the grammatical description of Maori.

In the first half of the 20th century Maori children were taught English at the expense of Maori. Influential Maori leaders advocated the use of English in Maori homes, and speaking Maori at school was often punished. By the mid-20th century Maori was rapidly dying, although small Maori-speaking communities remained in isolated rural areas. In 1951, Auckland University introduced Maori as an academic subject, which raised its status a little as did the grammatical descriptions produced by the linguist Bruce Briggs. However, the future looked bleak.

In the 1970s, a Maori political revival began (the 'Maori renaissance'). It was accompanied by serious endeavors to revitalize the language. *Kohanga reo* 'language nests' were established (preschool education centers providing education in Maori), and these were followed by Maori medium schools (*kura kaupapa Māori*), or immersion or bilingual units in mainstream schools. Small Maori radio stations were established with variable amounts of broadcasting in Maori. The Maori language became an official language of New Zealand. A Maori Language Commission was established to aid revitalization, and it has manufactured many vocabulary items from Maori elements to cater to modern needs. A Maori television channel went on the air in 2004.

Today the future of Maori is unclear. It might survive, testimony to the success of the revitalization process, but it is not yet secure. Most speakers have learned Maori as a second language, and many are 'semi-speakers.' Many teachers of Maori are not fully fluent, and the quality of the Maori taught in some Maori-medium classrooms is poor. Many children who leave *kohanga reo* speaking fluently do not use the language as teenagers. Most native speakers of Maori are over 70 years old, although there are some (particularly from the Tuhoe area, where Maori remained strong 20 years longer than elsewhere) still in the workforce. It is common to hear 'relexicalized English' – English structures where the content words and some of the grammatical words are replaced by Maori lexical items. Fluent Maori speakers often speak English to each other rather than Maori. While the latest surveys suggest that more people are speaking more Maori, there are very few who are fully conversant with the language. The last New Zealand census contained a question about use of Maori.

Such dialect differences as exist are tribally based. Most are lexical and phonological (with divergent realizations of phonemes rather than different phonological systems), and grammatical differences are not very significant.

Maori has a small phoneme inventory, with ten consonants (/p t k m ŋ r w f h/), and five vowels (/a e i o u/), each of which may be short or long.

Orthographically, all use the obvious single roman letters except for <ng> (for /ŋ/) and <wh> (for /f/). The proper analysis of the long vowels is debatable: they may be analyzed as clusters of identical short vowels (reflected in 'double vowel' orthography), or as separate phonemes (reflected in the macron orthography, which is now official): *Maaori* vs. *Māori*. Syllables are open, and there are no consonant clusters. All pairs of short vowels can occur in clusters, but some behave as one syllable and some as two. There are also longer vowel clusters. The rhythm is based on the mora (of form (C)V, where V is short), but stress operates with a bigger unit (C)V(V). Word stress is predictable, with syllables ranked according to the nature of the vowel. All content words contain at least two morae.

Maori has virtually no inflectional morphology and very little derivational morphology, although the allomorphs of the passive suffix have raised significant linguistic interest.

The syntax is surface VSO, but the most likely underlying word order is VOS, with a rule that normally moves all but the first phrase in a complex predicate to the right of the subject. The basic unit of syntax is the phrase, which has a grammatical particle indicating the phrase function preceding the lexical material. Modifiers usually follow the lexical head. The grammatical particles include markers of tense and aspect, and prepositions that indicate noun-phrase function, and may be tense-marked. The sentence subject is the only NP without an introductory preposition. Maori does not have a copular verb, and many sentences lack overt verbs. The basic syntax is illustrated in the following:

kei	raro	ngā	pukapuka	tawhito
at-PRES	*underside*	DEF.PL	*book*	*old*
a	Hone	i		
DEF.PL.APOSS	*John*	*at*. TNSNEUTRAL		
t-ō-na	moe-nga			
DEF.SG-OPOSS-3SG	*sleep*-NOML			

'John's old books are under his bed'

ka	tope	a	Wāka	
FUT	*chop*	PERS ART	*Wāka*	
i	te	rākau	rimu	a
ACC	DEF.SG	*tree*	*rimu*	*at*.FUT
te	Rāhina			
DEF.SG	*Monday*			

'Wāka will chop down the rimu tree on Monday'

The pronoun system distinguishes singular, dual, and plural, and in the first person, inclusive and exclusive. Number is marked on determiners, not nouns (except for a handful of personal nouns), the singular usually with an initial *t-* and the plural with Ø (e.g., *tētahi* – sg, *ētahi* – pl) and there is a special determiner for proper names. There is a very complex system for the expression of ownership, including a distinction akin to alienable/inalienable (marked by *a-* vs. *o*-forms). Most lexical items can serve without morphological change in noun phrases, verb phrases, or as modifiers. In narratives, the passive is used for most event sentences, which has given rise to much debate about ergative vs. accusative syntax. A typologically unusual feature is that lexical modifiers of passive verbs take a passive suffix in agreement with the verb. The direct object is not integrated into the grammatical system of Maori in the way that would be expected if the language was originally accusative: for instance it cannot normally be relativized on directly. This is probably one remnant of a former ergative syntax.

Mapping Syntax Using Imaging: Problems and Prospects for the Study of Neurolinguistic Computation

D Embick, University of Pennsylvania, Philadelphia, PA, USA
D Poeppel, University of Maryland, College Park, MD, USA

© 2006 Elsevier Ltd. All rights reserved.

Noninvasive imaging techniques fall into two classes: hemodynamic (positron–emission tomography, or PET; functional magnetic resonance imaging, or fMRI) and electromagnetic (electroencephalography, magnetoencephalography). A primary thread in imaging research has been directed at identifying brain areas associated with subcomponents of linguistic competence, such as phonology (Poeppel, 1996), syntax (Stowe *et al.*, 2004), and semantics (Bookheimer, 2002). Research in this area makes extensive use of hemodynamic imaging because the impressive spatial resolution offered by such techniques (millimeter scale) lends itself naturally to functional mapping. Here we examine a set of findings that implicate Broca's area – the canonical language area – in syntactic processing and review the extent to which recent results converge in a way that is interpretable from the perspective of the language sciences. Our focus is on the experimental and conceptual issues that render results from imaging difficult to interpret. We put aside discussion of the more technical problems that confront functional imaging studies, including issues associated with the experimental design (e.g., subtraction methodology), analysis (complexity and potential arbitrariness of criteria in data analysis), and implicit assumptions about the relationship between loci of activation and cognitive systems.

The activation of Broca's area has been reported in many studies of both syntactic comprehension and production (Caplan *et al.*, 1998; Dapretto and Bookheimer, 1999; Embick *et al.*, 2000; Friederici *et al.*, 2000; Friederici, 2002; Homae *et al.*, 2002; Indefrey *et al.*, 2001; Kaan and Swaab, 2002; Kang *et al.*, 1999; Moro *et al.*, 2001; Musso *et al.*, 2003; Newman *et al.*, 2003; Ni *et al.*, 2000), from which it has been concluded that this area has a privileged status with respect to this aspect of grammar. One complicating factor is the use of different terminologies in identifying the relevant cortical regions. In particular, there are reports in terms of both Brodmann areas (i.e., BA 44/45) and in terms of gyral and sulcal anatomy (pars opercularis, pars triangularis; also F3op, F3t). Because these definitions are not coextensive, there is a potential for terminology-induced confusion. This situation is in principle capable of being remedied by making reference to standardized coordinate systems, such as the atlas of Talairach and Tournoux (1988), although this process itself is not unproblematic because of the anatomical transformations that are required for such a standardization. The identification of 'Broca's area' in such terms ranges in Talairach coordinates from $x-28$ to -55, $y-8$ to $+34$, and z 0 to $+28$ (even without including studies that take BA 47 to be part of Broca's area). It seems, then, that the great variability found in the discussion of this area precludes any straightforward biological interpretation.

Specific studies that associate Broca's area with syntax employ a number of different design types. Dapretto and Bookheimer (1999) used fMRI in a block design and presented sentences auditorily to subjects, who performed one of two tasks. In the 'syntactic' condition, the task was to judge whether two sentences – one active (*the policeman arrested the thief*) and one passive (*the thief was arrested by the policeman*) – were the same or different. In a 'semantic' condition, subjects judged 'same' for two sentences that differed by a single word (*the lawyer/attorney questioned the witness*) or (*the lawyer/driver questioned the witness*). Activation in BA 44 was reported for the comparison syntax minus semantics (as well as syntax minus rest), and activation in BA 47 for semantics minus syntax. Auditory presentation was also used in the event-related fMRI study performed by Ni *et al.* (2000). Subjects performed syntactic and semantic oddball tasks, in which a sequence of grammatical sentences contained an occasional deviant oddball (syntactic: **trees can grew*; semantic: #*trees can eat*). Activation in BA 44/45 was reported for the subtraction of semantics from syntax. The PET study of Moro *et al.* (2001) used a block design with visual presentation; the task involved silent reading and acceptability judgments on four types of Italian sentences. In addition to a baseline of Jabberwocky (*il gulco gianigevale brale*), there were three types of violation: word-order (**gulco il gianigevale brale*); morphosyntactic (**il gulco ha gianigiataquesto bralo*); and phonotactic (**il gulco gianigzlevale brale*). Activation for the syntactic and morphosyntactic conditions minus the phonotactic condition was found in left BA 45 and right BA 44/45. Kang *et al.* (1999) used an event-related design with fMRI; subjects were presented visually with phrasal stimuli containing syntactic and semantic violations. The stimuli were verb phrases like *drove cars* (the normal condition), in addition to which there were two deviant conditions: syntactically deviant **forgot made* and semantically deviant **wrote beers*. Relative to the normal condition, activation was found for both the

syntactically and semantically deviant stimuli in BA 44/45; the activation in left BA 44 was greater for syntax than for semantics.

In addition to the studies using anomaly detection/judgment outlined above, activation in Broca's area has been reported in studies of the syntax of artificial language learning (Musso *et al.*, 2003) as well as in studies of syntactic complexity (Caplan *et al.*, 1998). Musso *et al.* taught subjects artificial 'grammars' with two distinct types of rules. One type was a rule found in natural languages but not in the language of the subjects. A second type of rule involved a string manipulation of a type that is not attested in the world's languages. Subjects were asked to perform an acceptability task on visually presented sentences. Results showed increased activation in BA 45 for the first type of rule (real) in comparison with the second type of rule (unreal). Musso *et al.* concluded from these results that Broca's area is specialized for the learning of syntactically possible rules, independent of the age of the learner. Caplan *et al.* (1998) showed that syntactic complexity effects (measured in terms of processing time differences) are reflected in an increase in signal in Broca's area. They concluded that this region is specialized for the processing of certain aspects of syntactic structure.

The activation of Broca's area (defined as BA 44/45) in a number of 'syntax' studies employing distinct tasks and designs seems at first glance to confirm the claim that this area is specialized for syntax. There are two further considerations, however, that suggest that this conclusion is at best an oversimplification.

First, Broca's area has been reported to be active in a number of linguistic tasks that are not syntactic: tasks ranging from lexical tasks, for instance auditory lexical decision (Zatorre *et al.*, 1992; Poeppel *et al.*, 2004) and studies of minimal pairs in tone languages (Gandour *et al.*, 2000), to phonological/phonetic tasks, such as the discrimination of rapid phonetic transitions (Fiez *et al.*, 1995) or the processing of phoneme sequences as opposed to hummed notes (Gelfand and Bookheimer, 2003). The role of Broca's area in phonetics/phonology is reviewed in Burton (2001). The claim that Broca's area is exclusively devoted to syntax is thus incorrect, although the possibility that Broca's area might be specialized for language in some broader sense is left open.

The second consideration that complicates the view of a syntactic Broca's area is the fact that Broca's area is active in a number of entirely nonlinguistic tasks. The tasks include motor activation (Iacoboni *et al.*, 1999), motor imagery (Binkofski *et al.*, 2000; Hamzei *et al.*, 2003), and rhythmic perception (Halpern and Zatorre, 1999; Platel *et al.*, 1997). These findings constitute a challenge to the weaker position that Broca's area is specialized for language in the broad sense.

The interpretation that identifies Broca's area as responsible for syntax is informed by sources of evidence other than imaging studies: deficit-lesion studies, electrophysiological studies, clinical findings, and so on. From the imaging studies, it is clear that a simple association between Broca's area and syntax cannot be maintained. At the same time, the apparent set of contradictions generated by imaging studies cannot be surprising given a realistic view of how cognitive functions, including syntax, are computed. In linguistic domains other than syntax, for instance, a complex internal structure is clearly required for processes such as phonetic and phonological analysis, lexical analysis, and so on. Therefore the expectation that syntax should be a simplex, unstructured computation associated with a single undifferentiated cortical region is unrealistic. While it is clear that some of the computational subroutines that are essential for syntactic processing/production are computed in the inferior frontal gyrus (IFG), these are not syntax *per se*; they are subcomponents of syntax. What is required is a theory of these computations at the correct level of abstraction or granularity, a theory that seeks to associate these computations with different subparts of Broca's area. For example, two components essential to syntax are the creation of hierarchical structures and a process that linearizes these hierarchical structures. Computations of this type may be factored out of syntax in the broad sense and are perhaps associated with different subparts of the IFG. The natural assumption is that differently structured cortical areas are specialized for performing different types of computations, some of which are necessary for language but also for other cognitive functions. For instance, the activation of 'mirror neurons' in the IFG has a role in motor action/imitation, but this activation also is relevant to the linguistic domain in the context of 'forward' models of speech perception (Halle and Stevens, 1962). Some preliminary proposals making distinctions among subregions of BA 44/45 are found in Horwitz *et al.* (2003).

In conjunction with an appropriately granular theory of the computations performed in the brain, the spatial information provided by imaging has the potential to illuminate aspects of the biological foundation of language by providing the critical link between specialized cortical areas and cognitively relevant types of computations.

Mapudungan

F Zúñiga, University of Zurich/University of Leipzig/Centro de Estudios Públicos, Zurich, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

The dialects of Mapudungu(n), less deviant from one another than the dialects of English, are spoken by the Mapuche of south-central Chile and central Argentina. Current conservative estimates place the number of fluent speakers at one-third of the almost 1 000 000 ethnic Mapuche; more than 90% are in Chile, of which more than 40% are in or around Santiago and only 30% live in the traditional Mapuche territory. The main present-day dialects are (1) Mapudungun proper or Central Mapudungun, in south-central Chile, and (2) Pehuenche, to the east of the former. Further dialects such as Argentinean Ranquel and Chilean Picunche and Huilliche are either obsolescent or extinct. Other names for the language are Araucanian (from *araucanos,* the ethnonym used by the Spaniards; present-day Mapuche avoid using this term), Mapuchedungun, and (Re)chedungun. Several genetic affiliations have been proposed, not only with languages spoken in the south of the continent such as Kawésqar (Qawaskar) and Yaghan (Yámana) but also with language families as distant as Arawak, Carib, and Mayan; to date, none of these proposals has been convincingly substantiated. The first grammar dates from the early 17th century. Written texts began to appear in the early 1900s and have become more numerous only at the end of the 20th century.

The phoneme inventory is simpler than the ones found in neighboring languages: the vowels are /a, e, i, o, u, ɨ/ (where /ɨ/ <ü> is unrounded high central when stressed and close to a schwa when unstressed). The glides are palatal /j/ <y>, labiovelar /w/, and velar /ɰ / <g>. The consonants are the voiceless unaspirated noncontinuants /p, t̪<t̲>, t, ɻ<tr>, c <ch>, k/ (where /c/ is alveolopalatal) , the voiceless fricatives /f, θ <d>, s <s, sh>/, the nasals /m, n̪ <n̲>, n, ñ, ŋ <ng>/, and the liquids /l̪ <l̲>, l, ʎ <ll>, ɻ<r>/. The dental series /t̪, n̪, l̪ / contrasts with the alveolar one /t, n, l/ only in highly conservative speech; most speakers have an alveolar series only. Pehuenche has voiced fricatives [v] and [ð] instead of [f] and [θ]. Primary stress can be largely predicted from syllable structure (it tends to fall on the penultimate mora) – with some exceptions, as in a number of disyllabic adverbs whose stress is lexically assigned to the ultima. Because there is no universally accepted orthographic convention, it is not uncommon to find some variation in the literature and deviant spellings such as <z> instead of <d> (for /θ/), <g> instead of <ng> (for /ŋ/), and <(t)x> instead of <tr> (for /ʈ/) in recent texts.

Nominal morphology is simple and almost exclusively derivational; there is neither gender nor case, adjectives take the suffix *-ke* in the nonsingular, and human nouns are marked with a preposed element *pu* in the plural. Compounding is highly productive, for example,

mapu-che
land-people
'people of the land'

Personal and possessive pronouns distinguish three persons (first, second, and third) and three numbers (singular, dual, and plural). Noun classes, possessive classes, classifiers, and alienable/inalienable possession are not marked overtly.

Agglutinative and predominantly suffixing, verbs are marked for mood (indicative *-i*, subjunctive *-l* and unmarked imperative), tense (future *-a* and unmarked nonfuture), evidentiality (reportative-mirative *-rke*), polarity (negative *-la* ∼ *-no* ∼ *-ki* and unmarked affirmative), directionals (e.g., cislocative *-pa*, translocative *-pu*, andative *-me*), voice (e.g., applicatives *-ñma* and *-(le)l*, reflexive *-w*, agentless passive *-nge*, causativizer *-m*), aspectuality (e.g., habitual *-ke*, progressive/resultative *-(kü)le*, progressive *-meke*, continuative *-ka*, telicizer *-tu*, ambulative *-(k)iaw*), modality in the broad sense (e.g., ruptured implicature *-fu*, immediate action *-fem*, sudden action *-rume*), and person. Person marking is intricate and can be described as following a direct/inverse pattern in that, when more than one argument is involved, the one ranking higher in the nominal hierarchy or primary argument (first- and second-person over third-person) and proximate over obviative on chiefly pragmatic grounds) is fully marked for person and number, whereas the lower or secondary argument is either underspecified or only implied. There are also forms that do not typically occur as predicates in main clauses; they do not encode the primary argument on the verb (but, with the exception of the *lu*-form, take an external possessive marker instead), function as verbal nouns, participles, and/or gerunds and end in *-n*, *-el*, *-lu, -yüm,* or *-am*. Many suffixes are transparently related to verb roots that still occur as such in the language (e.g., *meke-* 'be busy,' *tu-* 'take,' *kiaw-* 'walk,' and *fem-* 'do so'), and root serialization is used in order to express path of motion and other categories, for example,

rüngkü-kon-
jump-enter-
'jump in'

Reduplication of the root with *-tu* or *-nge* is used for the iterative, for example,

rüngkü-rüngkü-tu-
jump-jump-PRT
'jump repeatedly'

The incorporation of complex NPs is receding in the speech of younger urban Mapuche, but is productive in the speech of older rural speakers, for example,

ngilla-kurü-kal̲-ufisha-
buy-black-wool-sheep-
'buy wool of black sheep'

On the other hand, the incorporation of simple NPs into the verbal complex is still robust, as in

katrü-kachu-
cut-grass-
'cut grass'

Adjectives, wh-words, and numerals can all take verbal morphology.

Mapudungun is head-marking at both the NP level (possession) and the clause level. Unmarked utterances tend to be verb-initial and have at most one argument NP. There are both prepositions and postpositions, and adpositional phrases tend to follow the predicate and its arguments. Almost all marked word-order patterns are attested, and all can be elicited; an interplay of direct/inverse marking and position governs the interpretation of NPs as agentive or patientive. There do not seem to exist overt topic or focus markers, but a number of particles are used in questions or as intensifiers. Clause-linkage patterns resort to the gerunds previously mentioned or show coordination (e.g., with *ka* 'and' or *welu* 'but') or juxtaposition.

Although the lexicon of Mapudungun has visibly borrowed from Quechua and Spanish, the effects of contact on the morphology do not appear to be significant. The use of the verbal suffix *-fi* as more or less matching the use of the Spanish preposition *a* with direct objects and the higher frequency of AVO sentences in present-day Mapudungun are the most prominent contact-induced phenomena in the syntax.

Marathi

K Wali, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Marathi, a member of the Indo-Aryan subbranch of the Indo-Iranian branch of the Indo-European languages, is the official language of Maharashtra state of India. It is spoken by nearly 96 million people, according to the most recent census. The major dialects of Marathi are Deshi, spoken around Pune, Varhaḍi and Nagpuri, spoken around Nagpur, and Kokni in the coastal region. Marathi has been much influenced by Dravidian Kannada and Telugu spoken in the southern vicinity of Maharashtra (Bloch, 1920; Southworth, 1971).

History

Marathi is a direct descendent of Maharashtri, a prakrit language derived from Sanskrit. The earliest reference to spoken Marathi is found in *kuvalaymala* written in the 8th century by Udyotansuri . The earliest written Marathi is found in the 10th-century inscriptions at Shravan belgola. The earliest literary text is considered to be *Viveksindhu* of Mukundraja (1199 C.E.) A high literary form of Marathi appears around

Marathi

K Wali, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Marathi, a member of the Indo-Aryan subbranch of the Indo-Iranian branch of the Indo-European languages, is the official language of Maharashtra state of India. It is spoken by nearly 96 million people, according to the most recent census. The major dialects of Marathi are Deshi, spoken around Pune, Varhaḍi and Nagpuri, spoken around Nagpur, and Kokni in the coastal region. Marathi has been much influenced by Dravidian Kannada and Telugu spoken in the southern vicinity of Maharashtra (Bloch, 1920; Southworth, 1971).

History

Marathi is a direct descendent of Maharashtri, a prakrit language derived from Sanskrit. The earliest reference to spoken Marathi is found in *kuvalaymala* written in the 8th century by Udyotansuri . The earliest written Marathi is found in the 10th-century inscriptions at Shravan belgola. The earliest literary text is considered to be *Viveksindhu* of Mukundraja (1199 C.E.) A high literary form of Marathi appears around

the 13th century in *Jnaneshawari*, a commentary on the *Bhagavad Gita* (Master, 1964).

Script

Modern Marathi script, called *balbodhi*, is based on the Sanskrit Devnagari script, with certain modifications. Unlike English, Devnagari is alphasyllabic. It uses certain dicritics for vowels when combined with consonants. The dicritics distinguish long and short vowels. There is a also special system to denote consonant clusters. There also is an alternative cursive script, called *modii*, which was introduced by Hemadpant around the 17th century and was used in official documents for some time.

Phonology

Traditional Marathi alphabetic chart lists 16 vowels and 36 consonants based on Sanskrit. Today, many of these alphabets are obsolete. Modern Marathi has 8 basic vowels and 34 consonants, including two semivowels. Tables 1 and 2 indicate the vocalic and consonantal charts and their respective features.

A salient feature of consonants is the distinction between affricates and palatals. The distinction is neutralized before y and i. The origin of affricates is controversial, because they are not found in Sanskrit.

Suprasegmentals

Length:

Vocalic length is mostly predictable. With the exception of ə, the last vowel of a word is long unless the vowels are followed by a combination of consonants such as *nt, tr, kt*. (iii) The length is phonemic in *i, u*.

Nasal vowels:

Use of nasal vowels as independent entities varies from speaker to speaker. They are found in certain adverbs, nouns, and plural nouns in the context of case and postpositions. They are phonemic in certain dialects.

Accent:

Marathi is said to have a stress accent. Length, pitch, and sonority play a role in determining the loudest accent. (For details, see Kelkar, 1958, 1997; Pandharipande, 1997.)

Table 1 Vowels

	Front	*Central*	*Back*
High	i		u
Mid	e		o
Mid low	ai/æ	ə	au/ɔ
Low		a	

Salient features: The qualitative difference between ə and *a* is not precise. ə can be extra short and silent. *e* and *o* occur in all positions. *æ* and ɔ are found mostly in borrowings from English.

Morphology

Both animate and inanimate nouns exhibit two numbers – singular and plural – and three genders – masculine, feminine, and neuter. Marathi is a split ergative language. The subject is marked nominative with the exception of (i) transitive verbs in the perfective, (ii) obligative subjunctive, and (iii) dative verbs (Wali, 2004). The subject is marked ergative in (i and ii) and dative in (iii). In all these constructions, the verb agrees with the unmarked nounphrase, which may be a direct object or a theme. The verb shows neutral agreement if both subject and object have overt case. A salient feature of ergative system is seen in the pronominals. The first and second person pronouns are not overtly marked for ergative case and still show an ergative agreement pattern. What is more interesting is that the second person shows agreement for both nominative object and ergative pronoun though it is marked nominative (1). (See Wali, 2004.)

(1) tu — you-NOM
səməya — lamps-NOM-3FPL
ghas-l- ya-s. — wash-PERF-3FPL-2SG

'You washed the lamps.'

Syntax

Word Order

The standard word order is subject object and verb, that is, SOV, in all constructions including the interrogatives. The order is variable with certain restrictions. Most adjectives precede and agree with the nouns. Adverbs precede the verb. Some adverbs agree with the verb.

Passivization

There are two types of passives: regular and capability. Although both are formed by adding *ja* 'go' to the verbal perfective, there is a difference. The former applies only to the transitives and allows demoted agent to be deleted. The latter operates across intransitives and transitives and does not allow the demoted agent to delete.

Subordination

The subordinate clause may be finite or nonfinite. It may precede or follow the main clause. Adverbial and relative clauses are correlative type. The latter allow deletion of head and correlative nouns and show a considerable range of word order variation (Wali, 1982). They exhibit a reduced participial form in all

Table 2 Consonants

	Labial	*Dental*	*Retroflex*	*Alveolar*	*Alveopalatal*	*Velar*	*Glottal*
Stops							
vcl.unasp	p	t	ṭ			k	
vcl.asp.	ph	th	ṭh			kh	
vcd.unasp	b	d	ḍ			g	
vcd.asp	bh	dh	ḍh			gh	
Affiricates							
vcl.unasp				c	č		
vcl.asp.					čh		
vcd.unasp.				j	ǰ		
vcd.asp.				jh	ǰh		
Nasals	m	n	ṇ				
Laterals		l	ḷ				
Trill				r			
Fricatives		s	sh				h
Semivowels		v/w			y		

Salient features: *h* is a voiceless aspirate after voiceless stops and voiced aspirate in other positions. *s* becomes retroflex before a retroflex consonant. *v* vacillates between bilabial and labiodental position. It becomes a voiced lenis labiodental spirant in the intial position.

tenses. They also show a rare pattern of multiple headed relatives. These do not allow participial reduction.

Notion of Subject

The agreement is not a criterion for a subject because of the complexity noted in morphology. It is necessary to resort to other grammatical rules such as reflexivization, participle reduction to determine the subject. Both nominative and ergative subjects undergo the same rules. However, the status of dative and passive subjects is enigmatic since they obey only some of these rules. In fact, the rule criterion leads to the conclusion that these two construction may have two subjects contrary to the traditional notion of there being a single subject in a sentence (see Wali, 2004).

Not much is known about the life of Michael of Marbais (latinized, with many variants, as Michael de Marbasio, de Brabantia, or Michael modista). His name points to the village of Marbais, north of Charleroi, province of Brabant, Belgium. Kelly (1995: x) argues that Michael may be identical with the brother Michael de Helenchines listed in 1272 in the records of the Cistercian abbey of Villers-en-Brabant, the erection of which had been encouraged in 1146 by Judith of Marbais, a town

roughly 3 miles to the south. Sources show that this Michael came from, or was born near, the Premonstratensian abbey of Heylissem at Opheylissem (Hampteau in French), Hélécine, now part of Orp-le-Grand in the Wallonian part of Brabant, southeast of Louvain and approximately 30 miles northeast of Villers. The Premonstratensians were close to the Cistercians in their rites and even accepted lay members.

Michael, an independent mind who had a critical look on the work of Boethius of Dacia, wrote his influential grammatical treatises as a Master in the Parisian arts faculty between 1280 and 1300. He belongs to the second generation of the so-called modists who worked on speculative grammar with its key term of *modus significandi*. His grammar is based on a highly abstract 'physical' motus-model, which considers language as a series of processes. Michael was well aware of his pioneering role in the modistic conception of linguistics as a science. Since the time of the humanists (who did not like his opinions), his name is sometimes conflated with that of Johannes Josse de Marvilla. Besides the *Summa modorum significandi* (written ca. 1285, edited by Kelly) there are his earlier *Tractatus super grammaticam* and *Quaestiones super Priscianum minorem*, both only extant in manuscripts (cf. Bursill-Hall, 1981).

Markedness

L R Waugh and B A Lafford

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 5, pp. 2378–2383, © 1994, Elsevier Ltd.

Many linguistic phenomena consist of polar opposed pairs: for example, the phonological feature unvoiced–voiced, the antonyms *long–short*, the grammatical relations singular–plural and active–passive. In such binary oppositions (contrasts), moreover, the poles are not usually mere opposites: typically there is an asymmetry, such that one pole may be more special or specialized, more focused or constrained, less general and more complex than the other. In such cases, the specialized element is said to be marked, the more general one unmarked: in the examples given above, the unmarked element is given first, the marked element second. This is related to observations such as the following: nouns are listed in the singular in dictionaries, since the plural is considered to be a special use; unvoiced [s] is more common in English than voiced [z]; the active sentence *John hit the ball* is simpler than the passive *the ball was hit by John; how long is that stick?* is normal, but *how short is that stick?* is used only under special circumstances. Markedness is correlated with the asymmetric relationship between two choices, whether in phonology, morphology, syntax, or semantics; furthermore, it is important in other areas such as historical linguistics, first/second language acquisition, stylistics, etc.

Mark-up Languages: Speech

J Kusnitz, IBM Almaden Research Center, San Jose, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Until fairly recently, the web has primarily delivered information and services using visual interfaces, on computers equipped with displays, keyboards, and pointing devices. The web revolution had largely bypassed the huge market of customers of information and services represented by the worldwide installed base of telephones for which voice input and audio output provided the primary means of interaction.

VoiceXML 2.0 [VXML2], a standard recently released by the W3C [W3C], is helping change that. Building on the market begun in 1999 by the VoiceXML Forum's VoiceXML 1.0 specification [VXML1], VoiceXML 2.0 and several complementary standards are changing the way we interact with voice services and applications by simplifying the way these services and applications are built.

VoiceXML is an XML-based [XML] language, designed to be used on the Web. As such, it inherits several key features common to all XML languages:

- It leverages existing Web protocols such as HTTP to access remote resources.
- Any tool that is able to read or write XML documents can read and write a VoiceXML document.
- Other XML documents can be embedded in VoiceXML documents and fragments; similarly, VoiceXML documents can embed other XML documents and fragments. This the case with SRGS and SSML, which are described later.

As mentioned above, VoiceXML 2.0 is one in a number of standards that the W3C Voice Browser Working Group is defining to enable the development of conversational voice applications. The specifications making up the Speech Interaction Framework are the following:

- Speech Recognition Grammar Specification 1.0 [SRGS]
- Speech Synthesis Markup Language 1.0 [SSML]
- Semantic Interpretation for Speech Recognition 1.0 [SISR]
- Call Control Markup Language 1.0 [CCXML].

This article provides a short introduction to VoiceXML, as well as SRGS, SSML, and SISR, for building conversational web applications. CCXML is an XML-based language exposing telephony and call control functionality for such applications as conference call bridges and call routing. CCXML, however, is beyond the scope of this article.

Building Conversational Applications using VoiceXML

Menu Element

Most VoiceXML dialogues are built from one of two elements. The first of these is the <menu> element. A VoiceXML menu behaves much like a collection of HTML links.

A VoiceXML menu has a <prompt>, which contains SSML content, and one or more choices, each identified by a <choice> tag. Each choice consists of a phrase indicating what the user can say, as well as a link to the next VoiceXML document to be executed.

Consider this <menu> example:

```
<vxml version = "2.0" xmlns = "http://www.w3.org/2001/
  vxml">

  <menu>
    <prompt> Say one of: <enumerate/></
  prompt>
    <choice next = "http://www.example.com/
  sports.vxml">
      Sports scores
    </choice>
    <choice next = "http://www.example.com/
  weather.vxml">
      Weather information
    </choice>
    <choice next = "#login">
      Log in
    </choice>
  </menu>

</vxml>
```

Here is one possible path through this dialogue:

Browser: Say one of: Sports scores; Weather information; Log in.
User: Sports scores

When the VoiceXML Browser recognizes that the user has spoken 'sports scores,' it fetches the VoiceXML document identified by the corresponding choice (http://www.example.com/sports.vxml) and begins executing it, presumably providing the user with sports information.

Form Element

The second dialogue element in VoiceXML is the <form> element. A VoiceXML form is very similar to an HTML form in that it typically contains one or more input fields that a user must complete. Each input field in a form has a prompt and a specification of what a user can say to fill in the field.

A sample "login" form might look like this:

```
<vxml version = "2.0" xmlns = "http://www.w3.org/
  2001/vxml">

  <form id = "login">

    <field name = "phone_number" type = "phone">
      <prompt> Please say your complete phone
      number</prompt>
    </field>

    <field name = "pin_code" type = "digits">
      <prompt> Please say your PIN code </prompt>
    </field>

    <block>
      <submit next = "http://www.example.com/
servlet/login"
        namelist = "phone_number pin_code"/>
    </block>

  </form>
</vxml>
```

When this form is executed, the dialogue flow would be:

Browser: Please say your complete phone number.
User: 800-555-1212
Browser: Please say your PIN code.
User: 1 2 3 4

As each <field> is executed, its <prompt> is played. Following the prompt, the user responds by speaking the requested information. When both fields in the form have been filled, the final block is executed. In this example, the <block> executes a submit tag, which sends the variables 'phone_number' and 'pin_code' to the 'login' servlet, in much the same way as a 'submit' button works on an HTML form. The servlet would then return a new document for the VoiceXML Browser to execute.

As mentioned above, each field specifies the set of acceptable user responses. Limiting the acceptable responses serves two purposes. First, it allows the responses to be verified and for help in the case of an invalid response to be provided locally without the delay of a round-trip over the network to the application server. Second, it is essential to achieving good speech-recognition accuracy – particularly over a relatively low-quality audio channel like a telephone – for the user input to be constrained to particular sets and patterns of words.

In the example above, the set of acceptable user inputs is specified implicitly using the 'type' attribute ("phone" and "digits" in the example) in the field element. The VoiceXML 2.0 specification defines a number of built-in types that a VoiceXML browser should optionally provide:

- boolean
- date
- digits
- currency
- number
- phone
- time

In addition to these built-in types, a VoiceXML application can specify its own input types using grammars. A grammar is essentially an enumeration in a compact form of a set of allowable phrases. The following VoiceXML fragment illustrates the use of grammars in an online voice-enabled restaurant application:

```
<form>

  <field name = "drink">
    <prompt> What would you like to drink?
      </prompt>
    <grammar mode = "voice" xml:lang = "en-US"
      version = "1.0"
      root = "drink">
      <rule id = "drink">
        <one-of>
          <item> coffee </item>
          <item> tea </item>
          <item> orange juice </item>
          <item> milk </item>
          <item> nothing </item>
        </one-of>
      </rule>
    </grammar>
  </field>

  <field name = "sandwich">
    <prompt> What sandwich would you like?
      </prompt>
    <grammar src = "sandwiches.grxml"/>
  </field>
```

```
    <block>
      <submit next = "http://www.example.com/
        servlet/getOrder"/>
    </block>

  </form>
```

Speech Recognition Grammars

The grammars in the previous example are specified using the W3C Speech Recognition Grammar Specification [SRGS] format. The first grammar is in-line, and it simply identifies a list of words and phrases ('coffee,' 'tea,' and so on) that the user may say in response to the prompt for that field. Surrounding the list of items with a <one-of> element tells the VoiceXML browser that the user can speak only one of these items at a time.

The second grammar is contained in the file "sandwiches.grxml" and is referenced via a URI:

```
<grammar mode = "voice" xml:lang = "en-US"
  version = "1.0"
  xmlns = "http://www.w3.org/2001/06/
  grammar" root = "sandwich">

  <rule id = "bread">
    <one-of>
      <item> rye </item>
      <item> white </item>
      <item> whole wheat </item>
    </one-of>
  </rule>

  <rule id = "ingredient">
    <one-of>
      <item> ham </item>
      <item> roast beef </item>
      <item> tomato </item>
      <item> lettuce </item>
      <item>
        <item> swiss </item>
        <item repeat = "0–1"> cheese </item>
      </item>
    </one-of>
  </rule>

  <rule id = "sandwich">
    <ruleref uri = "#ingredient"/>
    <item repeat = "0–">
      <item repeat = "0–1"> and </item>
      <ruleref uri = "#ingredient"/>
    </item>
    <item> on </item>
    <ruleref uri = "#bread"/>
  </rule>

</grammar>
```

This grammar consists of three rules. The first rule, named 'bread,' is just a list of bread types, similar to the 'drink' grammar, which was placed in-line in the form. It allows the user to say either 'rye' or 'white' or 'whole wheat.'

The second rule in this grammar, named 'ingredient,' is also a fairly simple list of items, but one of its items included an optional part. The last item in the rule includes a repeat attribute on the 'cheese' item, which makes 'cheese' optional. To match this rule, the user can say either 'swiss' or 'swiss cheese.'

The third rule, named 'sandwich,' specifies that a complete description of a sandwich consists of a series of rule references to the other rules defined within this grammar. It states that a 'sandwich' is made up of at least one ingredient, followed by zero or more additional ingredients optionally separated by the word 'and,' and ending finally with the word 'on' followed by the name of a bread. This rule would accept phrases such as 'ham and swiss on rye' and 'lettuce and tomato on whole wheat.'

A grammar's header is typically used to identify a single rule within the grammar as its 'root rule' via the 'root' attribute. This root rule is automatically activated when the grammar is referenced by a VoiceXML application, unless the application indicates that a different rule should be used.

The grammars in the previous examples were written in SRGS XML format. They could have also been written using SRGS Augmented BNF syntax. In addition to being a more compact, more human-readable form, grammars written in ABNF syntax are also more familiar to grammar developers.

An ABNF version of the sandwich grammar might look like this:

```
#ABNF 1.0 ISO–8859–1;

language en-US;
root $sandwich;

$ingredient = ham | roast beef | tomato | lettuce |
  swiss [ cheese ];

$bread = rye | white | whole wheat;

$sandwich = $ingredient ( [ and ] $ingredient ) <0-> on
  $bread;
```

A typical dialogue enabled by the above form and either of the grammars might be:

Browser: What would you like to drink?
User: Orange juice
Browser: What sandwich would you like?
User: Roast beef lettuce and swiss on rye

As with the previous form example, once the browser has collected the input for both fields, the final block will be executed and cause the variables 'drink' and 'sandwich' to be sent to the getOrder application for processing.

Speech Synthesis Markup Language

In each of the preceding VoiceXML examples, <prompt> tags were used to indicate text that would be synthesized by the browser and spoken to the user. The contents of each <prompt> are in Speech Synthesis Markup Language, or SSML. SSML not only allows a voice application developer to specify text to be synthesized but it also provides a means to specify prerecorded audio that should be played.

In addition, SSML has numerous parameters to control the output itself. There are parameters for controlling the output volume, the rate at which the synthesized text is spoken, what portions are emphasized, and so on.

A complete discussion of SRGS and SSML is beyond the scope of this article. For further reading, their respective specifications are a good starting point.

Use of Web Standards

As was mentioned previously, VoiceXML uses web standards, such as XML and HTTP. The power of the web lies in its ability to bring to each user a worldwide array of information and services and conversely to give each information and service provider a worldwide customer base. Thus, a distributed application model is fundamental to the web; VoiceXML builds on the same distributed model that has been so successful for visual web-based services.

The distributed web-based application model as used by VoiceXML services accessed by telephone is shown in Figure 1. The architecture for a voice application is the same as that of an HTML application. A browser, either VoiceXML or HTML, retrieves a page and then renders it for the user either audibly or visually; then the user responds, either via voice in the case of VoiceXML, or with the keyboard and mouse, in the case of HTML.

Additional Capabilities

In addition to the core capabilities described above, VoiceXML provides several more advanced features: local validation and processing, audio playback and recording, support for context-specific and tapered help, and support for reusable subdialogues.

Local processing and validation of user input are accomplished by a collection of elements that provide a more-or-less standard programming model. A 'block' element allows code to be run at any point in the process of collecting inputs. A <filled> element allows input validation code to gain control upon completion of any set of user inputs. This element is particularly useful for the mixed-initiative dialogue model, in which the user may supply inputs in any order, as described in a later section. Finally, a <script> element allows ECMAScript [ECMASCRIPT] (otherwise know as JavaScript) program fragments to be run locally at any point in the dialogue.

Playback of pre-recorded audio prompts is accomplished using the <audio> element from SSML. Recording of user messages is done with the 'record' element; the recorded audio may then be played back locally using the 'audio' element or uploaded to the server for storage, processing, or playback at a later time.

Context-specific and tapered help are provided by a system of events and event handlers. VoiceXML defines a set of events corresponding, for example, to a user request for help, a failure of the user to respond within a timeout period, or a user input that does not match an active grammar. The application may then provide in any given context, such as a form or a field, an event handler that responds appropriately to a given event for a particular context. Moreover, the help may be tapered: a count may be specified for each event handler so that a different handler is executed depending on how many times the event has occurred in that context. This feature can

Figure 1 VoiceXML in a typical web infrastructure.

be used, for example, to provide increasingly more detailed messages each time the user asks for help.

Finally, VoiceXML provides support for subdialogues. A <subdialog> is an entire form that is executed, the result of which is used to fill in an input item in the calling form. This feature has two uses: it may be used to provide a disambiguation or confirmation dialogue for an input, and it may be used to support reusable dialogues, shared across several VoiceXML applications.

Comparison with HTML

Although VoiceXML reuses many concepts and designs from HTML, it differs in several aspects because of differences between visual and voice interactions.

An HTML document is a single unit that is fetched from a network resource specified by a URI and presented to the user all at once. In contrast, a VoiceXML document contains several dialogue units – menus or forms – that are presented sequentially. This difference occurs because the visual medium is capable of displaying a number of items in parallel, whereas the voice medium is inherently sequential.

Thus, although a given VoiceXML document may contain the same information as a corresponding HTML document, the VoiceXML document will be structured differently to reflect the sequential nature of the voice medium. So, for example, the HTML equivalent of the menu in Example 1 above might be:

```
Please select a service.
<a href = "http://www.example.com/sports.html">
  Sports scores
</a>
<a href = "http://www.example.com/
  weather.html">
  Weather information
</a>
<a next = "#login">
  Log in.
</a>
```

In HTML, there is no need to identify this menu as a unit, though for accessibility reasons it is desirable to do so: XHTML2 has an <nl> (navigation list) element for exactly this reason.

VoiceXML, in contrast, requires dialogue elements (menus and forms) to be identified as distinct units so that they may be presented one at a time to the user. Thus, although an HTML document functions in effect as a single dialogue unit, a VoiceXML document is a container of dialogue units, such as menus and forms, and each contains logic to sequence the interpreter to the next unit.

Another consequence of the sequential nature of the voice medium is the need for the markup to contain application logic for sequencing among dialogue units. This is reflected in a tighter integration of sequential logic elements into VoiceXML than in HTML. For example, VoiceXML contains markup elements for sequence control, whereas in HTML, such control is only available through the relatively more cumbersome method of scripting.

Natural Dialogue

VoiceXML as presented above provides the capability for simple 'directed' dialogues, meaning that the computer directs the conversation at each step by prompting the user for the next piece of information. Dialogues between humans, of course, do not operate on this simple model.

In a natural dialogue, each participant may at various stages take the initiative in leading the conversation. A computer-human dialogue modeled on this idea is referred to as a 'mixed-initiative' dialogue because either the computer or the human may take the initiative in leading the conversation.

The field of spoken interfaces is not nearly as mature as the field of visual interfaces, so standardizing an approach to natural dialogue is more difficult than designing a standard language for describing visual interfaces like HTML. Nevertheless, VoiceXML takes some modest steps toward allowing applications to be built that give the user some degree of control over the conversation.

In each of the forms shown above, the user was asked to supply input by speaking a value for each field of a form in sequence. The set of phrases that the user could speak in response to each field prompt was specified by a separate grammar for each field. This approach allows the user to supply one field value in sequence.

Consider a form for airline travel reservations in which the user must supply a date, a city to fly from, and a city to fly to. A directed dialogue conversation for completing such a form might proceed as follows:

Browser: Where are you traveling from?
User: New York.
Browser: Where are you traveling to?
User: Chicago.
Browser: When would you like to travel?
User: . . .

By contrast, a somewhat more natural dialogue might proceed as follows:

Browser: How can I help you?
User: I'd like to fly from New York to Chicago
Browser: When would you like to travel?
User: . . .

VoiceXML enables such dialogues by allowing input grammars to be specified at the form level, not

just at the field level, and by further annotating the rules in the grammar to identify which portion of a user's input is intended for which field in the form. This annotation is accomplished through semantic interpretation.

Consider the following VoiceXML document:

```
<vxml version = "2.0" xmlns = "http://www.w3.org/
  2001/vxml">
  <form id = "traveling">

    <grammar src = "travel.grxml" type = "application/
      srgs + xml"/>
    <initial name = "get_info">
      <prompt> How can I help you? </prompt>
      <catch event = "nomatch">
        <prompt>
          Let's try getting each field separately.
        </prompt>
        <reprompt/>
        <assign name = "get_info" expr = "true"/>
      </catch>
    </initial>

    <field name = "from_city">
      <grammar src = "travel.grxml#fromWhere"/>
      <prompt>What city are you traveling from?
        </prompt>
    </field>

    <field name = "to_city">
      <grammar src = "travel.grxml#toWhere"/>
      <prompt>What city are you traveling to?
        </prompt>
    </field>

    <block>
      <submit next = "http://www.example.com/
        servlet/flyaway"/>
    </block>

  </form>
</vxml>
```

And here is the grammar that it references:

```
<grammar mode = "voice" xml:lang = "en-US"
  version = "1.0"
  xmlns = "http://www.w3.org/2001/06/
  grammar" root = "travel">

  <rule id = "travel">
    <item repeat = "0–1"> I'd like to fly </item>
    <one-of>
      <item>
        <ruleref uri = "#fromWhere"/>
        <ruleref uri = "#toWhere"/>
        <tag>
          $.from_city = $fromWhere;
          $.to_city = $toWhere;
        </tag>
      </item>
      <item>
        <ruleref uri = "#toWhere"/>
        <ruleref uri = "#fromWhere"/>
        <tag>
          $.to_city = $toWhere;
          $.from_city = $fromWhere;
        </tag>
      </item>
    </one-of>
  </rule>

  <rule id = "fromWhere" scope = "public">
    <item>
      <item> from </item>
      <ruleref uri = "#cities"/>
      <tag> $ = $cities </tag>
    </item>
  </rule>

  <rule id = "toWhere" scope = "public">
    <item>
      <item> to </item>
      <ruleref uri = "#cities"/>
      <tag> $ = $cities </tag>
    </item>
  </rule>

  <rule id = "cities">
    <one-of>
      <item> New York </item>
      <item> Chicago </item>
      <item> San Francisco </item>
    </one-of>
  </rule>

</grammar>
```

Although the grammar looks fairly complex, it is not really so. It differs from earlier grammars only in that it now has semantic interpretation information included within it, indicated by the <tag> elements throughout.

These tag elements determine what information is returned to the VoiceXML application when a rule is matched. If the rule "fromWhere" is activated, for example, and the user speaks the phrase "from San Francisco," the tag contents say that the fromWhere rule should ignore the word "from" and only return whatever the "cities" rule returned ($ = $cities). The cities rule, of course, would have returned the phrase "San Francisco" so the "fromWhere" rule would then also return "San Francisco."

Similarly, the more complex "travel" rule says that the user can say the optional phrase "I'd like to fly" followed by a phrase matching the fromWhere rule and then a phrase matching the toWhere rule, or even the converse.

As with the simple case, upon saying something that matches the rule of the grammar, the semantic interpretation information is then processed. The travel rule's <tag> element says that when a phrase is matched, the results of the $fromWhere and $toWhere rules are to be stored in the $.from_city and $.to_city variables, respectively. This action has a

special meaning when the grammar is being used as a form-level grammar, which is the case now. In this case, the VoiceXML Browser will fill the "from_city" field with the value from $.from_city, and the "to_city" field with the value from $.to_city.

When the VoiceXML application above is executed, the VoiceXML Browser will activate the form-level grammar and then execute the initial element, which will cause the "How can I help you?" prompt to be played. At this point, the user can either say a phrase that matches the grammar, such as "I'd like to fly from San Francisco to New York," or he or she can say something that does not match the grammar. In the former case, two semantic interpretation processing elements will result in the form's two input fields being filled in, followed by the execution of the submit element within the block.

In the event the user's input does not match the active grammar, the nomatch event handler will terminate the initial element processing and collect each field's input separately.

By further extending the grammar, any number of possible user inputs could be used to fill in the field information. For example, the fromWhere and toWhere rules could be made optional in the travel rule, allowing the user to speak, 'I'd like to fly from New York' without having to include 'to Chicago.'

The ability to accept such free-form utterances is only a first step toward natural dialogue. Over time, VoiceXML will continue to evolve to incorporate more advanced features in support of natural dialogue.

Multimodal Interaction for Rapid Task Completion

Multimodal interaction enables rapid task completion by enhancing the bandwidth of man–machine communication (Bolt, 1980; Cohen, 1992; Cohen *et al.*, 1997). Common use cases that drive multimodal Web interaction on emerging personal information appliances including PDAs and smart phones are:

- Use visual output to efficiently convey available choices.
- Enhance small-size displays with spoken output.
- Use spoken input to collect user intent.
- Use visual interaction to disambiguate spoken intent.

See Raman (2003) for details on multimodal use cases and the associated shift in the underlying user interaction paradigm.

All of these user scenarios are motivated by the need to augment the bandwidth of man–machine communication, especially when working with mobile devices or in a hands-free, eyes-free environment. The ability to augment visual interaction with the spoken modality leads to rapid task completion, since the user is able to better express intent using a combination of modalities that best match the user's needs and abilities at any given time.

Authoring Web Content

Web content is authored using declarative markup, e.g., HTML; such content is further styled using Cascading Style Sheets (CSS) (see Lilley *et al.*, 1998; Pemberton, 2000). In this combination, HTML markup represents the content; CSS style rules specify aspects of presentation such as fonts, colors, and margin settings. CSS is also capable of specifying aural properties via Aural CSS; thus, CSS can style output with respect to the voice used when handling spoken displays (see Raman, 1997).

special meaning when the grammar is being used as a form-level grammar, which is the case now. In this case, the VoiceXML Browser will fill the "from_city" field with the value from $.from_city, and the "to_city" field with the value from $.to_city.

When the VoiceXML application above is executed, the VoiceXML Browser will activate the form-level grammar and then execute the initial element, which will cause the "How can I help you?" prompt to be played. At this point, the user can either say a phrase that matches the grammar, such as "I'd like to fly from San Francisco to New York," or he or she can say something that does not match the grammar. In the former case, two semantic interpretation processing elements will result in the form's two input fields being filled in, followed by the execution of the submit element within the block.

In the event the user's input does not match the active grammar, the nomatch event handler will terminate the initial element processing and collect each field's input separately.

By further extending the grammar, any number of possible user inputs could be used to fill in the field information. For example, the fromWhere and toWhere rules could be made optional in the travel rule, allowing the user to speak, 'I'd like to fly from New York' without having to include 'to Chicago.'

The ability to accept such free-form utterances is only a first step toward natural dialogue. Over time, VoiceXML will continue to evolve to incorporate more advanced features in support of natural dialogue.

Multimodal Interaction for Rapid Task Completion

Multimodal interaction enables rapid task completion by enhancing the bandwidth of man–machine communication (Bolt, 1980; Cohen, 1992; Cohen *et al.*, 1997). Common use cases that drive multimodal Web interaction on emerging personal information appliances including PDAs and smart phones are:

- Use visual output to efficiently convey available choices.
- Enhance small-size displays with spoken output.
- Use spoken input to collect user intent.
- Use visual interaction to disambiguate spoken intent.

See Raman (2003) for details on multimodal use cases and the associated shift in the underlying user interaction paradigm.

All of these user scenarios are motivated by the need to augment the bandwidth of man–machine communication, especially when working with mobile devices or in a hands-free, eyes-free environment. The ability to augment visual interaction with the spoken modality leads to rapid task completion, since the user is able to better express intent using a combination of modalities that best match the user's needs and abilities at any given time.

Authoring Web Content

Web content is authored using declarative markup, e.g., HTML; such content is further styled using Cascading Style Sheets (CSS) (see Lilley *et al.*, 1998; Pemberton, 2000). In this combination, HTML markup represents the content; CSS style rules specify aspects of presentation such as fonts, colors, and margin settings. CSS is also capable of specifying aural properties via Aural CSS; thus, CSS can style output with respect to the voice used when handling spoken displays (see Raman, 1997).

The move from the document-based HTML Web of the early 1990s to the application Web was enabled by the addition of event handlers to specific constructs on a page; such event handlers enabled Web authors to create content that reacts to user interaction events. The eventing model used to propagate such events and attach appropriate handlers has been standardized by the W3C in the DOM2 Events Recommendation; XML-Events 1.0 is a W3C Recommendation that defines an interoperable XML syntax for authoring such event binding (see Pixley, 2000; Hosn and Raman, 2002; Pemberton *et al.*, 2002). Thus, document-centric HTML markup can be made interactive by attaching interaction behavior in the form of appropriate event handlers.

Event handlers are responsible for producing appropriate end-user behavior in response to events they handle; a simple example of such event handling is to change a background image in response to a mouse-rollover event. Event handlers provide a powerful means of attaching interaction behavior; today, event handlers are used for a variety of purposes that range from animating Web content to validating user input. Thus, event handlers, along with the underlying markup elements to which they are attached, together implement UI components within a Web page.

A first example of integrating spoken dialogs into visual Web content to enable multimodal interaction was described in X + V (Axelsson *et al.*, 2001); X + V provides a standardized authoring metaphor for attaching voice handlers to HTML content. The effect of attaching such voice handlers is to turn Web components e.g., HTML's ⟨**input**⟩ element, from being a purely visual components into multimodal components; with the addition of voice handlers, users can interact with the resulting components via spoken as well as visual interaction. We show an example of such a speech-enabled HTML component in Figure 1; for a detailed overview of authoring multimodal applications using this design pattern (see McCobb *et al.*, 2003). This approach to multimodal authoring has been implemented on many XHTML browsers including Opera and NetFront – a screenshot of a flight reservation application running on a Sharp Zaurus is shown in Figure 2.

Thus, a voice handler that is attached to an ⟨**input**⟩ component can play a spoken prompt, activate an appropriate grammar for recognizing the user utterance, and finally, bind the recognized value to the ⟨**input**⟩ component. Next, we describe how such voice handlers can be authored in VoiceXML to bring high-quality Voice User Interaction (VUI) to the multimodal Web.

```
<form>
...
<label for="city">City:</label>
<input name="city" id="city" type="text"
  ev:event="focus"
  ev:handler="#voice_city"/>
...
</form>
```

Figure 1 A speech-enabled Web component. The component can be placed in a standard Web page to create multimodal interaction when consumed by a Web browser that implements the DOM2 Events loop. As an example, see the speech-enabled Opera browser.

Figure 2 The multimodal flight finder enables rapid task completion by enabling the user to interact via a multiplicity of user interaction modalities (http://www2002.org/CDROM/alternate/120/).

Dialogs – Voice User Interface Components

Dialogs form the building blocks of spoken interaction and provide an ideal abstraction for speech-enabling man–machine interaction. This insight led to the design of W3C's VoiceXML 2.0 (see McGlashan, 2003) – a declarative XML-based language for authoring voice interaction. VoiceXML dialogs form the basic building blocks of VoiceXML applications and are described in Kusnitz and Lucas (2004). In brief, VoiceXML dialogs enable the application designer create voice interfaces that exhibit rich interaction by providing capabilities such as tapered prompting and simple mixed-initiative dialogs.

VoiceXML dialogs were originally designed for use in voice-only applications; their initial use was to put together VoiceXML applications to create the voice Web. The key insight in the X + V design was to observe that these same voice dialogs, when used by themselves, could become the voice components needed to turn visual Web content into rich multimodal user interfaces.

Speech-Enabling Visual Web Content

As described earlier, declarative content authored in HTML can be made interactive by binding appropriate event handlers. VoiceXML dialogs can be attached as event handlers that respond to specific user interaction events e.g., on-focus to speech-enable HTML content. Using the standardized DOM2 eventing model as expressed via markup conforming to XML-Events creates a declarative authoring framework for multimodal applications. The DOM2 eventing model exposed by standards-compliant Web browsers enables visual and voice interaction components to participate as equals in creating a resilient multimodal interface. This results in user interfaces that enable rapid task completion along with robust error correction.

Consuming Multimodal Content to Gain Ubiquitous Access

Multimodal content, once authored for the standards-compliant Web, can be deployed and consumed in a manner best suited to the end-user's needs and abilities at a given time. All modern devices incorporate a Web browser as the preferred means for delivering user interaction; as these browsers catch up with the current W3C standards, content providers can deliver a rich multimodal user experience by wiring in standard user interaction components including voice dialogs authored in VoiceXML and rich visual content authored in Scalable Vector Graphics (SVG).

Such content can be consumed on end-user devices that implement the standard DOM2 eventing framework; user interaction events can be dispatched by the browser to software modules that can execute the specified event handlers. As an example, a multimodal application might bind voice dialogs as event handlers for the various user interaction components on a page; a browser that consumes such an application can dispatch the relevant events to an implementation that can invoke these handlers. A key consequence of this design is that handlers can be run locally on a device or on the network. Thus, application authors can create multimodal content that can be deployed to a variety of devices that range from laptops to extremely thin mobile clients that rely on network resources for compute-intensive tasks.

Conclusion

Ubiquitous access brings a whole new emphasis to the 'world wide' in the World Wide Web. Multimodality is crucial for delivering on the promise of ubiquitous access from an ever-increasing range of personal information appliances. Building on well-established and mature standards leads to a vendor-neutral platform that lends itself well to innovations that make our future dreams a reality. This phenomenon has led to an explosive growth in the availability of on-line content; the coming decade will see an ever-richer set of access capabilities that enhance our ability to leverage the WWW at work and play.

Mark-up Languages: Text

L Burnard, Oxford University, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

The word 'markup' was originally used to describe annotation or other marks introduced into a manuscript, for example by a copyeditor, in order to instruct a compositor or typist how a particular passage should be printed or laid out. Underlining of various kinds might be used to indicate boldface, special symbols to indicate passages to be rearranged, omitted, or printed in a particular font, and so forth. As document production became increasingly automated, the term came to be used also to describe the special codes inserted into electronic texts to govern analogous tasks in the formatting and printing of documents. The rapid growth in the development of computer text processing systems during the 1970s also led to the development of increasingly formalized markup systems. Notable early examples of these include the GML troff system developed for the Unix operating system; the Generalized Markup Language developed by Goldfarb, Mosher, and Lorie at IBM to represent the structure of legal documents (Goldfarb, 1996); the TeX language developed specifically for the typesetting of mathematics by Donald E. Knuth (Knuth, 1984); and a document formatting system called Scribe developed by Brian Reid at Carnegie-Mellon University (Reid, 1980).

These and other systems greatly influenced the transition from *ad hoc* or proprietary systems of conventional codes to the highly influential Standard Generalized Markup Language (SGML). This ISO standard, which defined a metalanguage for the definition of specific markup vocabularies and grammars for their deployment, had an influence far beyond its original remit of simplifying production and maintenance of technical documentation.

A key feature of these early document-processing systems was the recognition that the concepts instantiated by a given document's markup might usefully relate not to its physical appearance but to its significance. This insight was seized upon by early theoreticians of markup who argued forcefully that markup should be used to encode the real structure of a document, independent of how that might be realized in some specific instance or version of it (Coombs *et al.*, 1987). It was held to be more useful (for example) to mark that a stretch of a document was a heading than to state that it should be printed in boldface and centered, not only on practical grounds deriving from the inherent reusability and plasticity of electronic documents, but also on theoretical grounds relating to the nature of text itself.

Early adopters of the SGML standard included some rather strange bedfellows, with little in common beyond a major investment in computer-held text: the U.S. Department of Defense and the American Association of Publishers, for example. In 1987, an international research project known as the Text Encoding Initiative also adopted the standard as the means of expressing a set of guidelines for those preparing machine-readable texts in literary and linguistic research (Sperberg-McQueen and Burnard, 1994). During the 1990s, the notions of markup embodied by SGML became particularly influential with the development of the World Wide Web and its associated markup languages HTML (Berners-Lee, 1992) and XML (Bray *et al.*, 1998), both of which derive from SGML. The development of the World

The word 'markup' was originally used to describe annotation or other marks introduced into a manuscript, for example by a copyeditor, in order to instruct a compositor or typist how a particular passage should be printed or laid out. Underlining of various kinds might be used to indicate boldface, special symbols to indicate passages to be rearranged, omitted, or printed in a particular font, and so forth. As document production became increasingly automated, the term came to be used also to describe the special codes inserted into electronic texts to govern analogous tasks in the formatting and printing of documents. The rapid growth in the development of computer text processing systems during the 1970s also led to the development of increasingly formalized markup systems. Notable early examples of these include the GML troff system developed for the Unix operating system; the Generalized Markup Language developed by Goldfarb, Mosher, and Lorie at IBM to represent the structure of legal documents (Goldfarb, 1996); the TeX language developed specifically for the typesetting of mathematics by Donald E. Knuth (Knuth, 1984); and a document formatting system called Scribe developed by Brian Reid at Carnegie-Mellon University (Reid, 1980).

These and other systems greatly influenced the transition from *ad hoc* or proprietary systems of conventional codes to the highly influential Standard Generalized Markup Language (SGML). This ISO standard, which defined a metalanguage for the definition of specific markup vocabularies and grammars for their deployment, had an influence far beyond its original remit of simplifying production and maintenance of technical documentation.

A key feature of these early document-processing systems was the recognition that the concepts instantiated by a given document's markup might usefully relate not to its physical appearance but to its significance. This insight was seized upon by early theoreticians of markup who argued forcefully that markup should be used to encode the real structure of a document, independent of how that might be realized in some specific instance or version of it (Coombs *et al.*, 1987). It was held to be more useful (for example) to mark that a stretch of a document was a heading than to state that it should be printed in boldface and centered, not only on practical grounds deriving from the inherent reusability and plasticity of electronic documents, but also on theoretical grounds relating to the nature of text itself.

Early adopters of the SGML standard included some rather strange bedfellows, with little in common beyond a major investment in computer-held text: the U.S. Department of Defense and the American Association of Publishers, for example. In 1987, an international research project known as the Text Encoding Initiative also adopted the standard as the means of expressing a set of guidelines for those preparing machine-readable texts in literary and linguistic research (Sperberg-McQueen and Burnard, 1994). During the 1990s, the notions of markup embodied by SGML became particularly influential with the development of the World Wide Web and its associated markup languages HTML (Berners-Lee, 1992) and XML (Bray *et al.*, 1998), both of which derive from SGML. The development of the World

Wide Web to its current pre-eminent position can be attributed partly to its reliance on a simple descriptive markup language, which, moreover, was defined independently of any of the software used to produce or process it. The transition from the limited semantics of this HTML language to the more flexible and well-designed extensible markup language XML is further demonstration of the power of the ideas originally put forward in the SGML standard. At the time of writing, XML is the de facto standard for the representation of complex textual data in almost every new system, and is also the channel of preference when data of any kind is to be communicated between systems.

If the function of markup is to describe what a text really is or is thought to be (Renear *et al.*, 1996), the process of marking up a text is essentially one of annotating its constituents with some indication of how they should be identified and interpreted, which can then be used by a subsequent user of the text, such as a piece of software displaying or analyzing it. As such it is a fundamentally linguistic and interpretive process. At a banal level, all printed texts are marked up in the sense that punctuation marks, use of capitalization, disposition of letters around the page, even the spaces between words, function as a way of helping the human reader determine where one word ends and another begins, or how to identify gross structural features such as headings, and syntactic units such as dependent clauses or sentences. Encoding a text for computer processing may simply formalize these visual signals in a more rigorous manner; more generally, however, it will enrich them by providing non-obvious annotations representing (in some sense) the results of an interpretive process, by marking up the reading of a text, rather than its visually salient features.

This tension between what are (for some) self-evident structural features of a text, and the potentially contentious interpretations or classifications of those features that others identify in them, or in their interstices, is at the heart of the whole markup enterprise, as it is (in a sense) at the heart of any other hermeneutic endeavor. One advantage of using a formal markup language such as XML is that its expressivity is precisely delimited, and can be automatically validated. XML markup has a very shallow semantics, expressing little more than labeled bracketing of content within a single hierarchy. Because the interpretation of the labels (the element names) used within an XML vocabulary does not form part of XML itself, the creator of an XML document is effectively required to define all the distinctions made within it, either explicitly or by reference to some predefined standard such as that of the TEI.

At the most primitive level, texts are composed simply of streams of encoded data (characters or bytes of data, marks on a page, graphics, etc.): these are known as entities in SGML. At a higher level of abstraction, a text is composed of representations of elements of various kinds, linguistically or functionally defined. Elements do not appear randomly within a text: coherence demands that particular types of element appear in specifiable relationship to others – they may be included within each other, linked to each other by reference, or simply presented sequentially, for example. The rules defining how elements may legally be combined in a particular class of texts is known as a document type or schema.

An XML markup language comprises a list of element names, each of which may also bear a set of named attributes, together with rules stating how element occurrences may legally be combined. A valid XML document is a single element (the root element) containing either unmarked textual data, or a mixture of other elements, each properly nested within its parent. For example, a <conversation> element might contain a series of <utterance> elements, each of which might carry a speaker attribute. Within each utterance element, individual words or phrases might also be marked, perhaps with attributes to indicate their syntactic or morphological function.

In an XML document, the start of each element occurrence is marked by a start-tag, which contains the name of the element type and also specifies any attributes applicable to the element. The end of an element occurrence is also marked explicitly by means of an end-tag. XML defines a simple invariant syntax for the representation of XML occurrences. For example:

```
<conversation>
<utterance speaker='Mutt'>My dog's got no
  nose.</utterance>
<utterance speaker='Jeff'>How does it smell?
  </utterance>
<utterance speaker='Mutt'>Terrible.</utterance>
</conversation>
```

The schema for this document would indicate that the element <conversation> may be used as the root of a document and that it must contain one or more <utterance> elements. It would also indicate that the <utterance> element may contain unmarked text and that it bears an attribute called speaker, the possible values for which might also be constrained, for example by reference to some other element (say, <person>).

It is easy to see how this markup might be further extended to include, for example, specification of word class and root form for the individual words:

```
<utterance speaker='Mutt'>
<w class='POS' root='I'>My</w>
<w class='NOUN' root='DOG'>dog</w>
<w class='AUX' root='HAVE'>'s</w>
<w class='VB' root='GET'>got</w>
...
</utterance>
```

or, without use of attributes:

```
<utterance speaker='Mutt'>
<w>
<class>POS</class>
<root>I</root>
<form>My</form>
</w>
<w>
<class>NOUN</class>
<root>DOG</root>
<form>dog</form>
</w>
...
</utterance>
```

Either of these XML representations conveys the same information as any of the various ways that the output of an automatic parser might be presented. Such systems typically associate a text form with its word class and root form (and sometimes other analytic codes as well) and produce output in an idiosyncratic format analyzable by only a limited range of software. Either XML representation, by contrast, can be processed by any XML-aware software without ambiguity; furthermore, both XML representations are functionally equivalent, and the choice between them may therefore be made on the basis of what is thought to be operationally more convenient to capture or to process.

XML markup is topologically very similar to other forms of labeled bracketing commonly used in linguistic formalisms to represent tree-structured data or data in linear form. Indeed, an XML document may be thought of as a special case of a directed acyclic graph, in which the nodes represent element occurrences and the edges define containment relations. XML can therefore also be used to represent syntactic or functional structures beyond the word level, or tree banks:

```
<utterance speaker='Mutt'>
<s><np>
<w class='POS'>My</w> <w class='N'>dog
  </w>
</np>
<vp>
<v>
<w class='HAVE'>'s</w> <w class='VB'>got
  </w>
</v>
<np>
<w class='NEG'>no</w> <w class='N'>nose
  </w>
</np>
</vp>
</s>.</utterance>
```

It is also possible to represent arbitrary links or alignments between parts of an XML structure by means of pointers. For example, in the example above, to represent that the word *it* has an anaphoric relation to the word *dog*, one could add an identifier to the latter and point to it from the former, like this:

```
<w class='POS'>My</w> <w class='N'
  xml:id='w123'>dog</w>
...
<w class='PN' ref='#w123'>it</w>
  <w class='V'>smell</w>
...
```

A frequently noted problem in this approach to the representation of full-scale linguistic analysis is that it is difficult to represent multiple analyses of the same phenomenon, if these fall foul of the requirement that the markup structure be well-nested (Barnard *et al.*, 1995). For example, in the analysis above, the price of making explicit that *'s got* functions as a single verb is that *dog's* disappears as a single orthographic unit. If one wished to add also (say) a prosodic analysis, or a discourse function analysis, the components of either of these would almost certainly not align exactly with utterance or word boundaries, nor with each other. Simple XML markup requires that one single hierarchic analysis of the text be privileged above others, and is thus not well suited to the direct representation of multitiered analyses. To overcome this problem, a number of varyingly unsatisfactory mechanisms have been proposed (DeRose, 2004), of which the most popular at present is the so-called stand off style of markup (Thompson and McKelvie, 1997), in which distinct analyses are represented by free-standing elements linked into the text by pointers. While comparatively lacking in robustness and also requiring special-purpose programming beyond the remit of standard XML software, it is claimed that such methods are sufficient to represent almost any kind of multiple analysis.

As these methods demonstrate, the scope of XML markup is not restricted to the delimiting of nested segments of text. It can also be used to represent complex analytic structures superimposed on or linked to a text, or even entirely abstract tree

structures, such as those used by some NLP systems to represent meaning, for example in a computational lexicon. Rather than regarding the analysis as an attribute of the word form, such systems regard the word form as an attribute of the analysis. There have been a number of attempts to reach a consensus on the vocabulary appropriate to describe such linguistic analyses (examples include EAGLES, ISLE), but the use of XML as a means of expressing them remains uncontentious. The approach to this problem recommended by the TEI Guidelines, also now in the process of standardization through ISO, is based on the use of the feature structure formalism (Carpenter, 1992), itself represented in XML (Lee *et al*., 2004). An XML representation of a feature structure analysis can be exchanged automatically between NLP systems without loss of information or ambiguity.

With the direct representation of meaning structures, distinct from the texts within which they are expressed or from which they are extracted, text markup seems to move into a different sphere of activity. But since all interpretations, even the abstractions within a computational lexicon, can be regarded as constituting some kind of text, perhaps this transition is neither difficult nor surprising.

roughly 3 miles to the south. Sources show that this Michael came from, or was born near, the Premonstratensian abbey of Heylissem at Opheylissem (Hampteau in French), Hélécine, now part of Orp-le-Grand in the Wallonian part of Brabant, southeast of Louvain and approximately 30 miles northeast of Villers. The Premonstratensians were close to the Cistercians in their rites and even accepted lay members.

Michael, an independent mind who had a critical look on the work of Boethius of Dacia, wrote his influential grammatical treatises as a Master in the Parisian arts faculty between 1280 and 1300. He belongs to the second generation of the so-called modists who worked on speculative grammar with its key term of *modus significandi*. His grammar is based on a highly abstract 'physical' motus-model, which considers language as a series of processes. Michael was well aware of his pioneering role in the modistic conception of linguistics as a science. Since the time of the humanists (who did not like his opinions), his name is sometimes conflated with that of Johannes Josse de Marvilla. Besides the *Summa modorum significandi* (written ca. 1285, edited by Kelly) there are his earlier *Tractatus super grammaticam* and *Quaestiones super Priscianum minorem*, both only extant in manuscripts (cf. Bursill-Hall, 1981).

Markedness

L R Waugh and B A Lafford

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 5, pp. 2378–2383, © 1994, Elsevier Ltd.

Many linguistic phenomena consist of polar opposed pairs: for example, the phonological feature unvoiced–voiced, the antonyms *long–short*, the grammatical relations singular–plural and active–passive. In such binary oppositions (contrasts), moreover, the poles are not usually mere opposites: typically there is an asymmetry, such that one pole may be more special or specialized, more focused or constrained, less general and more complex than the other. In such cases, the specialized element is said to be marked, the more general one unmarked: in the examples given above, the unmarked element is given first, the marked element second. This is related to observations such as the following: nouns are listed in the singular in dictionaries, since the plural is considered to be a special use; unvoiced [s] is more common in English than voiced [z]; the active sentence *John hit the ball* is simpler than the passive *the ball was hit by John; how long is that stick?* is normal, but *how short is that stick?* is used only under special circumstances. Markedness is correlated with the asymmetric relationship between two choices, whether in phonology, morphology, syntax, or semantics; furthermore, it is important in other areas such as historical linguistics, first/second language acquisition, stylistics, etc.

Markedness in Phonology

The first discussion of markedness in modern linguistics originated in the 1930s, in the writings of the Prague School structural phonologists Nicolai S. Trubetzkoy and Roman Jakobson. The essential insight is this: sounds are differentiated by binary phonological features, for example [p] vs. [b] (− voiced vs. + voiced) and [b] vs. [m] (− nasal vs. + nasal) in which the two poles of the feature are not on equal footing with each other: one is marked (e.g., + voice, + nasal), the other unmarked.

Markedness and Phonological Systems

Trubetzkoy argued that the unmarked value of a feature is that which is found in cases of internally conditioned neutralization—in those contexts where only one member of the pair can occur and the resulting neutralization is not determined by some feature of the context. Thus, for example, Russian has voiceless–voiced pairs of consonants such as [p–b t–d s–z], but in word-final position only unvoiced [p t s] can occur; so, voicelessness is unmarked. Trubetzkoy also noted another attribute of markedness, namely frequency: in general, unmarked categories have higher text frequencies than marked; thus, unvoiced stops are more frequent than voiced, orals than nasals, etc.

Further work in phonology has expanded on this nexus of properties to formulate the general principle whereby the unmarked feature is the one with wider paradigmatic and syntagmatic distribution. The unmarked category has a greater functional load than the marked: it is used to distinguish and identify a greater number of words than the marked one. The unmarked feature can usually enter into more types of combinations, and conversely the marked feature enters into fewer combinations and specifically tends not to be combined with other marks. For example, there are usually more oral consonants than nasal ones in a language (English has [p–b t–d k–g], but only [m n ŋ]), and often there is no velar or palatal nasal even though there is both a labial and a dental one (velars and palatals are marked vs. labials and dentals). Similarly, the typical five-vowel system [a e i o u] generally combines marked frontness with unmarked unrounding vs. unmarked backness with marked rounding. That is, much of the symmetry and asymmetry which is found in phonological systems can be explained by markedness.

The unmarked term also occurs in a greater array of syntagmatic environments, that is, it has greater freedom of occurrence. If one compares the allophonic (phonetic, contextual redundant) variation of phonemes, the unmarked phoneme tends to have more allophones than the marked one: for example, in some languages, voiceless stops have both aspirated and unaspirated allophones, whereas voiced ones do not (they are unaspirated). The basic allophone of a phoneme – the most frequent one and the least prone to assimilation by neighboring sounds – is also characterized by unmarked features: for example, in some languages both voiceless and voiced consonants are members of the same phoneme, and typically in such cases the basic allophone is the voiceless one (and consequently, linguists represent the phoneme by the voiceless sound).

Markedness and Crosslinguistic Comparison

Markedness relations are revealed not only by the behavior of the categories of one particular language, but also by a crosslinguistic comparison of types of phonological systems, and in particular by language typology and universals (as originally shown by Trubetzkoy and Jakobson). Such comparison gives evidence that some traits are basic, others less basic, and that the basic traits are also often the unmarked ones. Thus, some features are found in all or nearly all languages – for example, all languages have oral vowels, dental/alveolar consonants, and Consonant–Vowel (CV) syllables – whereas others are not, for example, only some languages have nasal vowels, palatal consonants, and CVC syllables. Moreover, there are types of linguistic systems which seem to occur quite regularly, and given these types, principles of dependency can be formulated; the most important is that of asymmetric implication: the presence of *x* implies the presence of *y* but not vice versa. In many cases, *y* is unmarked, *x* is marked – for example, the presence of the marked [ɲ] or [ŋ] in a language implies the presence of [m] and [n], but not vice versa.

Such principles have led to the reworking of phonological analyses of various languages. There was a famous application to reconstruction: proto-Indo–European (PIE) had been postulated to have an obstruent system with unmarked voiceless, singly marked voiced, and doubly marked voiced aspirated stops – but this violated the implicational law just given. Some subsequent reconstructions have eliminated the voiced aspirates, and have instead posited singly marked glottalized voiceless obstruents.

Such findings have also been crucial for predicting types and orders of phonological changes: in particular, the implicational universals mean that no language can acquire a marked category unless it acquires the unmarked one before (or concurrently); and no language can lose the unmarked category without first losing the marked. Moreover, there are specific tendencies: marked categories often arise out of the unmarked ones only in particular environments – that is, they are the result of conditioned change

(e.g., contextual assimilation) – whereas unmarked categories can be the result of unconditioned change. Thus, for example, (marked) nasal vowels typically arise through assimilation of an (unmarked) oral vowel to a succeeding nasal consonant, and then subsequent loss of the nasal consonant, whereas oral vowels can arise in a variety of different ways.

Universals and typological relations, especially implicational universals, also have explanatory power for first language (L1) learning by the child and for aphasic dissolution. For example, children tend to learn first the unmarked category and only later the marked one (they go from simpler to more complex sounds and systems): for example, [t] is learned before [k]; in like fashion, aphasics lose first the marked category and only later the unmarked one. Thus, there is a strong markedness connection between language structure, the universal and implicational distribution of categories within a language and across languages, the order of acquisition by children and of its loss by aphasics, and possible types of changes.

Such observations have led some to assimilate the notion of markedness with that of normality or naturalness, most explicitly in natural phonology: marked values are assumed to be unnatural – that is, more difficult to produce (more deviation from the neutral), more difficult to perceive (with attenuation of perceptual distinctions), more difficult to learn (learned later by children), more prone to instability (more likely to be lost over time).

It should be added that for some linguists not all marks are equally weighty and some marks are assumed to be heavier than others: e.g., glottalization is a heavier mark than nasality. And for still others binary markedness relations are not suitable for nonpaired phonemes: for example, for points of articulation as in [p–t–c–k] or vowel heights as in [i–e–ɛ–æ], some have postulated degrees of markedness.

Markedness in Morphology

Although the classic proposal about markedness was made in phonology, the notion has been richly explored for all aspects of language, most notably grammar (Jakobson, 1984 and Hjelmslev, 1953, 1972). In general, grammar exhibits many of the same criteria with the same interrelations: for example, frequency of occurrence, paradigmatic distribution and asymmetry of systems, syntagmatic distribution, language universals and implicational relations, types and orders of possible changes, order of acquisition in children and of loss in aphasia, etc.

In considering the singular (unmarked) vs. plural (marked), the following types of correlations to markedness have been found. There is a tendency toward fewer subcategories of the plural: in the English pronouns the singular shows gender differences (*he*, *she*, *it*) but not the plural (*they*) (this is known as syncretism/syncretization; *see* **Syncretism**; this is also tied to the expected relationship in implicational statements: for example, gender in plural pronouns implies gender in singular pronouns but not vice versa. In other words, in the singular there is a marked/unmarked relation such that *he* is unmarked vs. *she*, whereas the plural does not participate in the masculine/feminine opposition. The distribution of singular and plural is predictable: in running text, the singular is more frequent than the plural; and there is greater freedom of occurrence (wider distribution) for the singular. For example: in English the plural is used in fewer contexts than the singular; in Korean there is optional use of the plural in favor of the singular (the plural suffix on nouns is optional, so the singular form has either singular or plural meaning in context); in Hungarian the singular form of the noun is used when a number precedes the noun (this is sometimes known as contextual neutralization); in French the masculine plural is used to stand for both feminine and masculine (when an adjective agrees with both a masculine and a feminine noun, it is put in the masculine plural). The singular is learned earlier in L1 acquisition and disappears later in aphasic disturbances.

Markedness has also been used in morphophonemics (morphonology). Thus, the allomorphy represented by *cat/cats* is unmarked vs. the marked *foot/feet* for the following reasons: in the former there is no alternation of the root whereas in the latter the root alternates; in the former the morphological relation is segmentally represented (*cats*) but in the latter it is fusional (no segmentation possible); in the former there is phonologically conditioned, regular allomorphy for the plural and in the latter nonphonologically conditioned, irregular allomorphy. In fact, there is a general assumption that regularity is unmarked and irregularity marked, because of the following:

1. if both the unmarked and marked terms have allomorphy, there is less morphological irregularity of the marked term (e.g., in German the marked dative plurals uniformly have *-n* or *-en*, while the dative singular varies with gender and declensional class);
2. diachronic and synchronic regularization/leveling in child language, in pidgins and creoles, in dialects, and in informal speech (e.g., *foots* rather than *feet*);

3. the greater number of regular forms (the vast majority of nouns take the *-s* plural and only a small minority the irregular plurals);
4. the productivity of regular forms (e.g., new nouns coming into English normally take the *-s* plural *-sputniks*);
5. in language change, the singular provides the pivotal terms for analogical reformations (e.g., in popular French, the irregular plural *chevaux* 'horses' is replaced by regular *chevals*) and in pidgins and creoles, the plural is often dropped, especially if its formation is irregular, the old singular then being the only form of the noun (a new plural could then be added later based on this neutral form).

Considerations such as these have led to the development of the theory of natural morphology in which naturalness is explicitly tied to markedness and regularity.

Grammatical systems have been described in terms of markedness. The assumption is that there is a set of features and that one term of the system is unmarked (e.g., the simple present tense of English), whereas the others are marked, some of them singly marked (e.g., the simple past), others doubly marked (the past progressive), etc. In this way, hierarchies of markedness have been established. For certain systems, some linguists have argued for a nonbinary notion of markedness, such that there is a scale from more to less marked – for example, positive, comparative, superlative in *high, higher, highest*.

Syntactic Markedness

While much of the work on grammatical markedness has focused on morphology, there has been increasing attention to syntactic markedness. One famous early application was to word order: for example, the ordering relation between S(ubject) V(erb) and O(bject). It was found that one of the orders is unmarked (basic, dominant, preferred), the other(s) marked and used for special circumstances. For example, in English, SVO (*the man hit the ball*) and AN (*the red ball*) are the unmarked orders, and in German SVO is the unmarked order in main clauses, whereas subordinate clauses favor SOV. (In German there is markedness assimilation, which has been attested also in phonology and morphology: unmarked categories tend to occur in unmarked contexts, marked categories in marked contexts.) In languages with freer word order than English, the markings can be correlated with a variety of different contextual factors: for example, in Russian, the order of words depends on what the topic is, whether a noun is to be interpreted as definite or indefinite, etc., but SOV is obligatory if it is unclear which noun is S and which O. Moreover, a universal tendency has been noted whereby, in 99 percent of the cases, the S is before O, whether or not V intervenes: for example, SVO, SOV, and VSO are all widely attested, whereas OSV, OVS, and VOS are extremely rare: that this should be so is due to the greater saliency of S over O. Moreover, there are some general correlations between different types of orders: languages with unmarked VSO order are more likely to have unmarked NA and noun-genitive (possessor) orders, and prepositions rather than postpositions. Just as for phonology, work such as this has had a profound effect on the study of PIE and of language change and typology, where the mechanisms of change over time from one unmarked word order to another have been investigated.

There has been much interest in questions of the hierarchy of elements and their use in certain syntactic contexts. For example, work in syntax which has been inspired by prototype theory in psychology has defined the unmarked subject in terms of a bundle of categories: for example, it is animate, topical, agentive, singular, definite (thus, a sentence of the general pattern *John hit some balls* is more likely to be used than one of the general form *some balls hit the headmaster*) whereas marked subjects may differ in various ways from this prototypical combination. In fact, the notion of prototype is essentially an outgrowth of the fundamental notion of markedness, since with prototypicality there is a recognition of asymmetry among exemplars of a given category: like unmarked categories, prototypes are more basic, combine more freely and productively than do nonprototypes, are more frequent and more familiar, are more salient, have more autonomy, are the best examples of a given opposition, etc. That is, prototypes resemble unmarked terms in many respects, even if they are not strictly the same: for example, both singular and plural have prototypical uses, but the singular is the prototypical number category, because it is unmarked.

The association of marked terms with lesser universality and later learning by the child has received renewed attention recently in the relation between core grammar and universal grammar (UG). According to this theory, UG, which is made up of those grammatical (especially syntactic) phenomena which are found in all languages, determines a set of possible core grammars for languages by setting parameters, each with a finite number of values. These parameters may be connected through hierarchical relations of markedness or various implicational or preferential relations. Systems that fall within core grammar constitute the unmarked phenomena while more marked

elements are found in the periphery (for example, constituent orders with S before O are unmarked, those with O before S marked; unmarked use of prepositions with an object, e.g., *he came in the room*, vs. marked use of prepositions as adverb-like elements, e.g., *he came in*). In the acquisition of grammar and syntax in the child, UG is assumed to be innate, with unmarked options for parameters being preferred and learned first, the marked periphery of the system being learned later.

Grammatical Markedness and Second Language Acquisition

Based on the findings of L1 acquisition studies, several hypotheses have been proposed regarding the role of universal grammar and markedness (either intra- or interlinguistically) in second language (L2) acquisition. Most of the studies until the early 1990s have applied markedness concepts to crosslinguistic comparisons and notions of L1–L2 transfer predicted by the Contrastive Analysis Hypothesis in the 1950s and 1960s. The resulting formulation is the Markedness Differential Hypothesis (MDH) which proposes that the degree of difficulty in L2 acquisition may be attributed to the similarities and differences in typological markedness between second and first language. It is claimed that the MDH can predict relative areas of difficulty in the target language for learners with a particular first language. Scholars working in a UG framework propose that the difference in parameter settings between L1 and L2 may have an effect on the acquisition of the target language; however, the data also appear to support the idea that linguistic universals play a primary role in the acquisition process since learners from unrelated backgrounds demonstrate the same acquisition sequence when acquiring the same target language. The intralinguistic view of the role of markedness in L2 acquisition is also based on linguistic universals, whereby the less marked core structures are acquired early, and the more marked periphery structures later.

There is also evidence for markedness as an explanation for the development of grammatical patterns in the interlanguage (intermediate stages in the acquisition of a second language) of adult learners. For instance, adult L2 learners of Spanish acquire the present tense before the past and the indicative mood before the subjunctive. It is interesting to note that, just as for children, in interlanguage the unmarked forms often substitute for the marked categories before the latter are acquired. In addition, just as for aphasia, L2 attrition studies have found a relation between order of acquisition and language loss: for instance, in learners of English, the last question-forms learned (e.g., *whose*) are the first to be unlearned.

Markedness in Semantics

Work in grammatical and lexical semantics has often revolved around componential analysis and semantic features, which have been seen to mirror phonological and grammatical features in many respects; indeed, many of the criteria discussed above have been used (e.g., frequency, breadth of distribution, and prototypicality). The most important finding in semantics is the more limited range of meaning of the marked term and wider range of the unmarked: thus, while the marked term means the presence of a certain property *A* (e.g., *woman* states the presence of the marked category female), the unmarked may mean non-*A* in its main interpretation (e.g., *man* means male) or no signal of *A* at all (e.g., *man* in the sense of human being). Such relations have been shown to be ubiquitous in grammar: for example, the past tense is marked and signals past time; the unmarked present either signals nonpast (*John is here right now, John is coming tomorrow*), or time more generally (*the earth is round*). Further examples from lexical meaning include antonyms or complementaries from a number of different conceptual domains (although not all lexical relations are binary or involve markedness): for example, *good/bad, long/short, old/young*, as well as derivational relations such as *host/hostess* (e.g., *your hosts tonight are Mr and Mrs Smith*), kinship terms such as *mother* vs. *mother-in-law* and *stepmother*, etc. The asymmetry between marked and unmarked also enters into mathematical and logical symbolism: -5 is always negative, but 5 by itself can mean either the absolute value of 5, or $+5$; in logic, 'truth-value' means the truth or falsity of a given proposition. And, in certain fixed expressions, typically the order is unmarked then marked: *good and bad, high and low*, etc.

Markedness and Isomorphism

The correlation with markedness which is perhaps the most cited is that of isomorphism (iconicity) between form and content: formal complexity generally corresponds to conceptual complexity. For example, in general, an unmarked term will tend to either have zero expression or to be simpler in form than the nonzero or more complex marked term. Some examples are: in English, the singular of the noun has no overt expression (*cat*) but the plural has *s* (*cats*); words with derivational affixes are generally unmarked vs. their nonderived counterparts (e.g., *whiteness* is marked vs. *white*); in German, the marked

front rounded vowels (indicated by an umlaut) are associated with the marked categories of nominal plural, adjectival comparative and superlative, and verbal past subjunctive (e.g., *das Buch, die Bücher* 'the book, the books,' *hart, härter, härteste* 'hard, harder, hardest,' *er hatte, er hätte* 'he had, he should have'); and, in English, an active sentence has a simpler verb form and lacks the *by*-phrase of the passive and the verb *do* is used for (marked) negative, interrogative, emphatic predicates, whereas its absence is associated with the unmarked neutral predicate.

Of course, there are exceptions to this isomorphic principle in various languages, but these are typically seen to be rarer, abnormal, unnatural, and prone to instability: many types of language change or analogy (re)introduce isomorphism. For example, in Russian, where some of the doubly marked genitive plurals have no overt suffix, but the unmarked nominative singular does, many dialects have provided a complex, overt genitive plural: *jabloko* 'apple,' nominative singular vs. *jablok*, genitive plural, but dialectal genitive plural form *jablokov*.

Mark vs. Marker, Mark vs. Feature, and Contextual Markedness

Since the 1930s when markedness was first discovered, the original insight that marked and unmarked values are imposed on properties has been conflated with other closely allied phenomena by some linguists. For example, the overt expression of a grammatical category has been called a 'mark,' 'marker,' or 'marking,' or a form is said to be 'marked for' a given category if it is overtly expressed (e.g., *cats* is 'marked for' plural). This has led to some confusion when markedness and marker do not coincide, or when claims are made as to the theoretical importance of the correlation of these two factors.

Similarly, markedness has sometimes been equated with the presence of the plus value of a particular property (feature) and unmarkedness with its absence – i.e., being marked and having a feature are conflated. In other cases, markedness has been given up altogether and features treated as purely formal diacritics, as a classificatory scheme, in which the plus and minus values are symmetrical and interchangeable in principle. Therefore, for example, [+ voiced] is assumed to be marked by definition; *mother* is [+ female], {plural} [+ more than one], transitive verbs [+___NP], *pray* [+ human subject], *in* [+ containment] – and the plus feature is either by definition marked or markedness is not at issue. This evolution was due to a variety of factors. Early on, in phonology, for example, the presence of a given property (e.g., + voice) and especially of a secondary articulation (e.g., + glottalized) seemed by definition marked and their absence unmarked because there was an additional phonetic complexity to the marked sound which was missing in the simpler, unmarked one.

Other linguists claim, however, that mark and feature must be differentiated (the minus value of a feature may be marked), that marks can vary according to the simultaneous and/or sequential context, that the presence of an entity is not the same as markedness (thus, some secondary articulations may not always be marked), and that there are many phenomena that could not be explained withoutmarkedness. Considerations such as these led to major revisions in structuralist and generative phonology, beginning in the late 1960s. The basic change was to differentiate between mark and property/feature: a given feature (e.g., [+ voiced]) may be either marked or unmarked. If the markedness value is context-sensitive, there is a case of local or contextual markedness (markedness reversal or shift). Thus, for example, [+ voiced] is marked in stops and fricatives but unmarked in vowels (in English, voiceless vowels occur infrequently and only under special conditions – e.g., in whispering). Contextual markedness is also assumed to hold for combinations of segments: for example, voicing assimilation (e.g., agreement in voicing between all the consonants of a cluster) is unmarked, whereas lack of such assimilation is marked; thus, an unvoiced consonant is marked when in combination with a voiced one. In generative phonology (see Chomsky and Halle, 1968: ch. 9), such claims led to positing two levels of representation, a more abstract one in which features have the values U(nmarked) or M(arked) (e.g., U vs. M voiced in vowels), only M values contributing to the complexity of the grammar; and a less abstract one, derived from the first by marking conventions, which define the + / − values (U voice for vowels → + voice).

Contextual markedness and the differentiation of mark from feature have also been posited for grammar and semantics. In Frisian, singular is unmarked and plural marked for many nouns, but for a small class of nouns (e.g., body parts which come in pairs, domestic animals which usually occur in herds), plural is unmarked and thus served as the basis for analogical reformation. And, to use a crosslinguistic example, the nominative was the unmarked case in Classical Latin (it is the dictionary form and also the one used for book titles, etc.); but in Old French, which had a rudimentary case system (nominative vs. oblique), the nominative was marked, being used only for subjects, whereas oblique was unmarked; thus, for example, the modern French nominal forms come from the old obliques, not the nominatives (for a different point of view, cf. Mayerthaler, 1988: 50–65).

In like fashion, it has been argued that markedness shifts are prevalent in the lexicon: whereas there are many examples showing that the unmarked sex reference in English is male (as in *man/woman*), in animal names the female *cow* and *duck* are unmarked, whereas the male *bull* and *drake* are marked.

Such claims of reversals have proven to be controversial. For some linguists, grammatical and semantic markedness values can differ across languages and through time, but not in a given language at a given time: the plus value of a feature is always marked (thus *woman* in English is 'marked for' + female) and its opposite is not a minus value, but a zero value. Markedness is thus conflated with feature and no difference is made between unmarkedness and nonparticipation in an opposition (e.g., both *he* and *they* are 'unmarked for' + female). For others, phonological markedness values can shift from one context to another, but the value of a given feature in a given context is universal – for example, unvoiced vowels are always marked and unvoiced consonants unmarked. For still others, there are universal markedness conventions and language-specific deviations from them: the marked situation will not occur often nor be stable.

Other Examples of Markedness

Because markedness is correlated with issues of frequency, regularity, normality, and so forth, marked has also come to mean strange, deviant, unexpected, unusual in a given context, that is, stylistically marked: for example, some word orders are more literary, poetic, emphatic, etc., than others (the unmarked *I trust him* vs. the stylistically marked *him I trust*). The use of the present to refer to the past (the historical present, e.g., *and just as I was about to cross the street, John comes up to me and says* . . .) is a stylistically marked usage of the unmarked term. The inappropriate use of a form may be pragmatically marked: for example, *how do you do*? is unmarked when meeting someone new but marked in the middle of a conversation with a friend. In like fashion, categories may be sociolinguistically/socioculturally marked (e.g., nonstandard vs. standard usage, special jargon vs. everyday vocabulary); certain kinds of discourses/texts are marked (e.g., legal or scientific texts, performative speech acts); breaking the norms of a discourse type is marked (e.g., in cookbooks, the convention is that the directions go from start to finish and do not jump around), and so forth.

Concluding Remarks

Some linguists believe that markedness is a hallmark of human language precisely because it is a very simple idea which explains seemingly disparate facts in a variety of domains. They see simplicity and generality on the one hand and objective and empirical specificity on the other. But there are other linguists who feel that the original definition of markedness has been stretched so far as to be an unwieldy cover term for very different phenomena, especially since its definition changes across different theoretical traditions.

What has also proven to be controversial are the various attributes of markedness which have been discussed above: those who doubt the usefulness of markedness sometimes point to the proliferation of different criteria and their seemingly indiscriminate application to different domains. Those who use markedness debate about which attributes are necessary and/or sufficient to show markedness: for example, is one criterion all-important or is there more than one; if more than one, how do they interrelate; what if the criteria give conflicting results; are the criteria weighted or causally linked; are they absolute or probabilistic; are there degrees of markedness; can markedness be used for nonbinary sets; do the same criteria hold in all areas of language; etc.?

Indeed, this last question points to another area of controversy: namely, the range of application of markedness. Some restrict its application to just phonology or syntax, or see its validity within individual languages but doubt its universal applicability, while for others it can be applied both within a language and across languages. For some linguists it is a low-level theory needing explanation, whereas for others it is one of the major conceptual and explanatory achievements of contemporary linguistics. Finally, while some see it as strictly linguistic, others argue that it is a biological phenomenon, or that it is to be correlated with the cognitive and perceptual domains of prototypicality and perception (especially the figuremarked/ground-unmarked distinction), or they point to its application to human culture and to other symbolic/semiotic systems. Indeed, for these scholars, markedness is explanatory not just for language, but also for human behavior in general. They claim that it is a characteristically human trait to conceive of phenomena as binary and asymmetrical, that is, marked and unmarked.

Introduction

Marketing is an ambiguous domain within the scientific disciplines of economics, management science, and organizational studies (Kotler, 2003). First, marketing is mostly regarded as a functional part of every firm or organization, comparable to the administration or financial department, the production or service department, or the IT department. It is internal within a firm or company. Second, marketing is that process that connects outsiders, customers, or other companies to the firm itself. This implies that marketing is also (partly) external. Third, marketing is about the ways and processes – by texts, images, icons, and persuasion as well as deception – of selling products, services, and other activities to customers in general (Umiker-Sebeok, 1987).

The internal and partly external perspectives connect marketing to organizational issues, and the communication and transfer perspective connects marketing to psychology, management science, and communication. The ambiguity of the marketing domain returns in the relation between marketing and semiotics (Umiker-Sebeok, 1987). The organizational perspective is interesting for semiotics, because it deals with models, designs, and what Simon (1969) called 'artefacts or 'artificial structures.' And models, designs, and structures are kinds of sign or symbol systems. The psychological perspective returns in the discussion about the way products, services, and assets in general are advertised or communicated from the organization to the customer, via icons, symbols, pictures, and images (Hoytink, 2004). The characteristics of these signs are also an elementary part of semiotics.

The remainder of this article will keep this multi-interpretative domain of marketing in mind as it examines the nature of marketing and its relationship to semiotics.

To understand the role of marketing, we will first present the basic structure of a firm or company and the role of the marketing function. Then we will describe this structure as not something given, but something that develops and changes. Next, we will consider marketing as an artificial structure having special characteristics. Finally, we will take the field of semiotics and relate the various aspects of marketing that have been discussed with it.

The Firm as a Kind of Organization

Basically, a firm is a kind of organization. The essential characteristic of this kind of organization is that it is mostly working on a profit basis. As an organization, it can have many organizational forms, from a hierarchy to a clan. Many coordination mechanisms

Introduction

Marketing is an ambiguous domain within the scientific disciplines of economics, management science, and organizational studies (Kotler, 2003). First, marketing is mostly regarded as a functional part of every firm or organization, comparable to the administration or financial department, the production or service department, or the IT department. It is internal within a firm or company. Second, marketing is that process that connects outsiders, customers, or other companies to the firm itself. This implies that marketing is also (partly) external. Third, marketing is about the ways and processes – by texts, images, icons, and persuasion as well as deception – of selling products, services, and other activities to customers in general (Umiker-Sebeok, 1987).

The internal and partly external perspectives connect marketing to organizational issues, and the communication and transfer perspective connects marketing to psychology, management science, and communication. The ambiguity of the marketing domain returns in the relation between marketing and semiotics (Umiker-Sebeok, 1987). The organizational perspective is interesting for semiotics, because it deals with models, designs, and what Simon (1969) called 'artefacts or 'artificial structures.' And models, designs, and structures are kinds of sign or symbol systems. The psychological perspective returns in the discussion about the way products, services, and assets in general are advertised or communicated from the organization to the customer, via icons, symbols, pictures, and images (Hoytink, 2004). The characteristics of these signs are also an elementary part of semiotics.

The remainder of this article will keep this multi-interpretative domain of marketing in mind as it examines the nature of marketing and its relationship to semiotics.

To understand the role of marketing, we will first present the basic structure of a firm or company and the role of the marketing function. Then we will describe this structure as not something given, but something that develops and changes. Next, we will consider marketing as an artificial structure having special characteristics. Finally, we will take the field of semiotics and relate the various aspects of marketing that have been discussed with it.

The Firm as a Kind of Organization

Basically, a firm is a kind of organization. The essential characteristic of this kind of organization is that it is mostly working on a profit basis. As an organization, it can have many organizational forms, from a hierarchy to a clan. Many coordination mechanisms

can be used, such as standardization of tasks, power, or professional expertise. In organizational literature (Daft, 2000) it is argued that an organization (or a firm) exists because of the many processes that are carried out. Sometimes the processes themselves are conceived of as independent entities (Allport, 1962). Daft (2000: 12), for example, says that "organizations are social entities that are goal directed, are designed as deliberately structured and coordinated activity systems and are linked to the external environment." Sorge (Sorge and Warner, 2001) says that two meanings of organization should be discerned: social unity (or collectiveness) and organizational properties. In more general terms, an organization can be defined as the simultaneous functionalization and coordination of human actions with regard to objective goals. In this definition, the emphasis is on actions that can be integrated in tasks that in turn are constituting elements of processes (Gazendam, 1993; Thompson, 1967).

The recurring theme in definitions of organization is 'process,' or what is more relevant here – 'marketing process.' A process is an action in its progress. A process consists of tasks that are executed by human individuals. Besides the processes, human individuals or actors are the 'building stones' within organizations. We, therefore, view an organization as a multi-actor system (Gazendam and Jorna, 1998). An organization is rooted in the individuals that are part of the organization and can think for the organization. As Sorge (2001: 7) says: "Of course, there would not be any organization behavior without human behavior." The basic ingredients of an organization are the intelligent actors. This means that there exists a nesting of (a) actors within organizations, and (b) organizations within actors. The first nesting means that an organization always consists of a collection or group of actors (Gazendam *et al.*, 2003). This makes an organization a multi-actor system. The second means that a set of actors can form an organization, but only in the sense that an actor can think of and reason about what the **other** actors can do. The other actors in turn have opinions and beliefs, that is to say, representations, about the first actor. This implies that an organization as a construct consists of the overlap and sharing of individual representations. Organizations are the result of shared representations of actors.

The multi-actor (process) view of a firm puts individuals at the center of any organization, but also nested within processes. Roughly, two kinds of processes are discerned within any organization: 'primary' and 'secondary' processes. The primary processes are related to the main goal of the organization: hospitals are for curing people, bicycle factories for producing bikes, and trains for transporting people and goods. Secondary processes are the organizational processes that make things happen, from the IT department to the accounting department. Marketing is here again difficult to position. If it is related to matching products and services with customers, it is a primary process; without customers, firms do not exist for long. If marketing is related to the organizational processes of having the services and products delivered to customers, it is a secondary process. The developments of marketing over the last 50 years show a gradual change from mostly a secondary to more of a primary process. We will come back to this development later in this article.

A vital question for understanding the essence of the concept of a firm is: what are the essentials of being in business? Organizations are complex systems with many subsystems that are highly valued by all stakeholders: finance, production, research and development, human resource management, sales, services, after-sales, call-center, and the board of directors. Being in business, however, refers only to the ability to create a match between a product or service and a customer. Without this match there is no business. All subsystems aim to contribute to create this match, but none of them is critical. In principle, every subsystem can be outsourced. An entrepreneur can hire a person to handle finance, he can hire facilities for production, and even the board of directors can be regarded as only a formal, legally required instrument. The know-how to create this match is the real core of business – making sure customers find products and services and developing services and products for customers. It is this complex process that is the reason for the existence of marketing.

Marketing can therefore be a way of thinking as well as a way of acting. Marketing can, in fact, be organized in a formal department. Because of the complexity of many matching processes in the market, most companies have comparably complex organizational structures for this specific competence of 'making things happen.'

Although the fundamentals of marketing have existed through all time (it is often argued that being a marketer is the second oldest profession in history), the development of marketing as a professional activity has developed from the beginning of the 20th century. Especially after World War II, when abundance in the Western world was rapidly growing, the professionalization of marketing took place. In the next section, this development will be outlined. In this section, the basic and widely used interpretation of a professional marketing approach will be shortly introduced.

Marketing deals with buying processes and decision-making units of customers. In the recent

past, this seemed to require complex procedures and structures for which it was far too complicated to build reliable causal models to predict and manage the outcome. Therefore, the marketing professional was merely regarded as an artist – a magician able to develop successful advertising campaigns or the guru capable of designing that one desirable product every potential customer needed to buy. The need to manage all these marketing efforts demanded the development of systematic management techniques. Until the 1990s, there was only limited success for this effort. Marketers and their managers were destined to use less powerful approaches. Widely used and known by almost everybody in the marketing field is the so-called '4P scheme' (Kotler, 2003). A sound marketing plan should address at least four essential areas:

1. **P for Product**: A detailed description should be given of the product portfolio, including assortment choices, innovation plans, and product management;
2. **P for Price**: A profound pricing strategy dealing with price listings, negotiation tactics, and discount strategies;
3. **P for Promotion**: Only customers aware of the products can potentially become buyers; therefore, advertising, free publicity, and direct mail activities should be planned carefully;
4. **P for Place**: Referring to the distribution strategy, with decisions about which channels to the customers have be used – personal selling, mail, Internet, TV sales and so on.

It will not be easy to find a marketing plan, even today, that doesn't include these four Ps. They stand like an icon that is recognized by literally everyone in the field. In the next section, recent and fundamental improvements in marketing concepts will be outlined.

Developments in Views on Business and Marketing

Development of Marketing Concepts

Although the concept of the '4Ps' of marketing has been shown to be dominant and resilient over the decades, significant changes in the marketing paradigm have been documented. We can place the most important developments in an indicative timetable (Table 1). In every decade, characteristic developments in marketing thinking and typical management instruments are outlined.

In summary, over the past four to five decades the attention of marketers shifted from the bare transaction to building relationships with customers. It is believed that these relationships will produce many transactions over a long period of time. The aim towards loyal customers, referred to as 'defensive marketing,' will yield higher margins (Reichheld and Sasser, 1990). A customer becomes a loyal customer only after a strong relationship has been built. Frequent and well-planned contacts between the organization and the customer are essential. The

Table 1 Relations between Supplier, Customer, Actor (Agent) and Shareholder over four decades[a]

Decade(s)	*Focus*	*Graphical representation*	*Typical business concepts*
1960/1970	Transaction		4Ps marketing concept Quality management Customer retention Budgeting approach
1980	Competition		Value chain concept Strategic management Customer choice Resource allocation
1990	Shareholder		Financial value Rationalizing the business Customer loyalty Balanced Score Card
2000	Relations/Stakeholders		Interaction with customers Management of relations Customer experience Beyond budgeting

[a]Right arrow: directed; double arrow: interacting/competing.

organization is merely an experience to the customer; the company's value to the customer overrules the actual product value. This type of organization typically uses modern control techniques, like rolling forecasts or even the so-called 'beyond budgeting' (Waal *et al.*, 2004).

In the 1960s marketers fully focused on transaction. The match itself between product and customer was regarded the sole focus of the marketer. While from the 1990s on, there existed a 'buyer's market,' the 1960s were a typical 'seller's market.' The rise of 'quality management' (Juran and Godfrey, 1998; Crosby, 1992) is an example of the understanding that was typical for those years. High-quality products will sell themselves. The customer would choose the best product and was capable of keeping in mind from whom he bought the product. Customer retention was the only effect marketers intended to improve. Typical product-oriented advertising campaigns filled TV screens and newspaper advertisements. Control mechanisms were limited to classical budgeting techniques.

The 1980s showed important progress in marketing thinking. Due to the gigantic influence of the ideas of Michael Porter (Scott *et al.*, 1980; Porter, 1985) and Buzzell (Buzzell and Gale, 1987), marketers became aware of the fact that customers were capable of making choices. Strong emphasis was laid on competitive strength. Qualitative products needed a competitive advantage to be sold. Customers made choices, and influencing these choices was thought of as a strategic activity. Profitability was strongly related to the market share a company was able to realize. Strategic planning became more important than ever, and larger companies created formal strategic departments. Control mechanisms improved from simple budgeting into more intelligent resource allocation models.

The 1990s started in enormous abundance, everything (Western) mankind could dream of seemed to be achievable, until economic setbacks and technological frustrations did put business 'back to business' itself. A huge rationalization in management took place. Chief Executive Officers (CEOs) instituted enormous cost-cutting programs. A strong orientation to shareholder value and therefore on profitability was introduced at all levels of the organization. Control mechanisms like the Balanced Scorecard (Kaplan and Norton, 1999) clearly required the balancing of all expenses against the profitability of the company. Customer loyalty was important simply because loyal customers did improve profitability in a significant way (Reichheld and Sasser, 1990).

Specialization Areas in Marketing

Over the decades, the 4Ps became enriched by a paradigm shift from transaction to relation. The marketing field was influenced by the development of several areas of specialization. Scientists and practitioners experimented and documented these attempts quite well, and professionals realized that not all marketing efforts were alike. In stipulating these differences, new areas of marketing besides the traditional one between firm and customer were born and studied:

1. Business-to-business marketing
2. Not-for-profit-marketing
3. Marketing of services.

'Business-to-business marketing' strongly contrasts with business-to-consumer marketing. Consumer marketing deals with transactions (and relations) with the final customer, the user himself. Business marketing deals with transactions (and relations) upwards in the value chain. In business marketing, transaction processes are viewed as more rational, while consumer transactions are merely emotional. Business marketing deals with influencing decision-making processes, while consumer marketing emphasizes the impulse orientation of the consumer. As a result, in consumer marketing one typically speaks of sales management. Within business marketing, account management is the current practice. Basically, the fundamentals of marketing thinking do not differ, but the way in which they are applied is rather different (Webster, 1991).

Marketing is about earning money, and it has taken quite a bit of time for 'not-for-profit companies' such as the Red Cross, cancer foundations, or social activist organizations, to realize they also have customers. Not-for-profit companies also exist because they have the ability to have successful relationships with customers. The exchange in the transaction is different: money is given to the company in exchange for their promise to do something for a good cause – healing people, investing in fundamental medical research, or achieving other social goals. Customers have to be influenced to understand and value the mission of the organization and its well-being, although a direct benefit to the customer is often lacking. This is marketing in its very essence, and therefore has developed as a specialty (Ramaswamy, 1996; Shapiro, 1992).

'Marketing of services' is rather new, but today a 'product' is defined as "any product, service or idea that can be exchanged for another product, service or idea (preferably money)" (Pride and Ferrel, 1993; Lovelock, 1991). The difference between a product

and a service has strongly influenced marketing activities over time because a product is tangible and a service such as road-assistance contracts or a ticket to a football game is non-tangible. At the selling moment, a service only appeals to the imagination or existing representations of the customer. Service cannot be produced from stock, while products, like cars or bananas, can be produced from stock. For services, there is a strong emphasis in the sales process on creating an image for the customer. The mind, or rather the representations or images customers have, is where the marketer must contact the customer – or to put it in marketing terms – 'attack.' Again, major theories in marketing stay the same, but their applications and operationalizations are quite different, leading to a vast separate area of marketing expertise, i.e., services, as Lovelock (1991) showed.

Marketing as an Artefact

In his book *Sciences of the artificial* (1969), Simon demarcated the borders of a science of the artificial or 'artificial systems.' An artificial system is any system made by man, on purpose or not, that is designed, structured, and implemented – from city planning and countryside maintenance to television and radio programs. In fact, most systems in our everyday life are artificial. These systems can imitate the properties of natural systems without being themselves natural. Artificial systems are mostly expressed in terms of function, goal, and adjustment. We can discern simple and complex artificial systems. Simple artificial systems have a simple structure and their behavior can easily be predicted. Complex artificial systems are able to exhibit unpredictable behavior. Simple systems often are a part of complex artificial systems.

Marketing is a powerful artefact, but an artefact nonetheless. If we transfer the notion of the artificial to marketing, we can also distinguish simple and complex artificial systems. For example, it may be possible to assess the behavior of one customer for a certain marketing purpose, but doing the same for a large group of customers is extremely difficult. Customers may influence one another, customers do not have stable opinions, customers have partly contradicting opinions, and – on top of that – there is also a difference between marketing of products and of services.

The notion of artefact was also introduced by Simon to make a cross section through the 'monodisciplines.' Marketing itself does not belong to just one scientific field. It has relations with psychology, communication studies, economy, management studies, and business development, to name but a few. As a field of study, marketing is not tangible, and even for concrete products like cars or furniture, it can be positioned at the individual, the group, or the societal level: between seller and buyer, between customer and firm, and between firms mutually. As Nöth (2000) put it, marketing is by all means a form of symbolic action, or a conglomerate of symbolic actions, demarcated by the constraints of financial and legal structures. This perspective on marketing as an artefact and as a form of symbolic action brings us to the semiotic aspects of marketing. We see three relations with semiotics: (a) marketing (and firms) as semiotic structures themselves (Goodman, 1978), (b) assets, materials, goods, and services that are transferred by means of signs (Williamson, 1978) and (c) signs (brands, trademarks, or trade names) that are themselves treated as assets (Levy, 1978).

Semiotics and Marketing

Modeling marketing: Semiotics is of relevance for the modeling or designing of the processes, structures, depictions, and representations that we use in making sense of what we call a 'firm,' an 'organization,' or in more detail, a 'marketing activity.' In using labels, arrows, boxes, and connecting graphs on the one hand, and words and expressions on the other, we represent the trading and transaction activities that take place in what we call 'firms.' Two opposing positions can be discerned. First, the marketing models stand for what happens in man-made reality. This is a classical position in that the model is an adequate or true representation of marketing reality. Second, the other position states that the models create marketing activities. There is no true representation of reality – reality is created by the representation. The first can be called the 'positivist' position, and the second can be called the 'nominalist' or 'conceptualist' position. Most marketers do not look at their businesses in the second way; they mostly see them from a positivist perspective. You have something that you want to sell, and that means that you need a process that makes that happen. Models are needed to explain and predict what marketing does. However, in the last 15 years, the abundance of very sophisticated quantitative statistical techniques to assess customers and firms has increased so tremendously that often marketers do not know any longer what their models stand for. It seems that the techniques create realities. We call this relation of semiotics with marketing 'the modeling issue.'

Assets communicated by signs: The best-known relation of semiotics with marketing is the fact that every action of selling or buying has to be accompanied by texts, pictures, icons, diagrams, or gestures. The most common expressions are advertisements

(Holbrook and Hirschman, 1993; Larson *et al.*, 1991). This implies, first, an analysis at the level of pragmatics. What information in what wrapping is most effective in having my product or service sold? And should it be information, or should it be emotion, or feeling, or status? Second, there is also a semantic discussion involved here. What meaning or what sense can or should be given to certain products or services? Third, we are brought to the bottom semiotic discussion of what signs type are most effective in what setting. This ranges from icons, one-liners, and tunes to persuasive texts, humorous clips, and idols. Because marketing developed from transaction to relation, as we stated earlier, this process of communication, persuasion, advertisement, and false representation has become extremely important. Knowing a customer, connecting to a customer, and earning respect and trust from a customer require interpretation, knowledge-building, and establishing emotional contact with the customer. In this respect, modern developments in marketing are really working with semiosis (as sign interpretation and sign understanding), although we doubt whether any particular marketer will see it this way.

Signs as assets: Marketing is developing toward being an overarching field where communication, persuasion, information, deception, commercializing, and merchandising are strongly interconnected. If a firm invests a great deal of money to have its name, brand, or trademark deeply rooted in the minds of customers, the brand itself becomes of value. Logos and images are classical examples. In the perception of marketing as building a relationship with a customer instead of only selling a service or product, the relationship itself is the value of a firm. This value is not the price of the product or service, but a deeply felt representation of the customer that a firm is doing the best it can to entertain, support, and elaborate this relationship. When Shell underrated the manipulation possibilities of customers when it decided to sink the Brent Spar (a big oil storage platform) and then changed its decision, it realized that the image of Shell – its representation in the eyes of the customers – was an asset. Many other examples – from Coca-Cola changing its products to Microsoft taking viruses and spam more seriously than they had previously – can be found where a sign – the representation – is a bigger asset than the profit, turnover, or sales of the firm.

Marketing is a relatively new interdisciplinary domain in which theory development has just started. It had been basically connected to (profit) firms, but emerged in the service, governmental, and not-for-profit domains of society. Marketing has a mixed position in everyday life because, on the one hand, it communicates and informs, but on the other hand, it uses propaganda and deception. It will continue to work with signs of all kinds, but these signs will become more dynamic, more complex, and more combined in order to reach new citizens and consumers who are increasingly accustomed to working with the latest innovations in information and communications technology devices.

Marketing: Semiotics

W Nöth, Universität Kassel, Kassel, Germany

© 2006 Elsevier Ltd. All rights reserved.

Marketing is communication between marketers and consumers, with the purpose of directing the flow of products, services, information, ideas, and emotions from producers to consumers; it creates, satisfies, and reacts to demands, desires, and fashions of the marketplace in a process that involves the exchange of cultural, economic, and ideological values (Kotler, 1987: 3; Werner, 2004). The study of signs, meanings, and communication in the processes of marketing and the consumption of goods is a research field of applied semiotics, the 'semiotics of marketing' (*see* **Semiotics: History**).

Signs and Messages of the Marketplace

Marketing is not possible without language. The art of selling and creating involves a verbal rhetoric and a vocabulary of its own, and the word formation of brand names is a complex branch of linguistics with special relevance to marketing and economics in general (Piller, 2000). However, the marketplace is also the locus of countless nonverbal signs, whose study requires analytical tools of a general theory of signs. The gestures and facial expressions of the vendors and sales promoters are part of a nonverbal rhetoric of marketing; visual and musical messages support advertising campaigns in the media with nonverbal means; product and packaging design makes the object of exchange a material message, whose sender is the marketer and whose receiver is the consumer (Fritz, 1994; Nöth, 1998); logos and trade marks are indices both of a brand image and of corporate identities that contribute to the easy identification of the product in the multitude of goods available in the marketplace (Semprini, 1992; Gallert, 1998); and facts and myths concerning the utility and quality of the product, propagated by advertising campaigns, create a brand image that results in a complex semantics of goods (Aronoff, 1985). The marketplace is a stage of nonverbal communication, a communicative space where marketers and consumers meet to exchange goods, ideas, and values; it is everywhere in consumer societies, at home (mail, newspaper, telephone, television), in the street (machines, street vendors), at the local supermarket, the shopping mall, the industrial fair, the office, or on the World Wide Web.

Survey of Semiotic Approaches to Marketing

Semiotics, the general study of signs and sign processes, has provided analytical tools for the analysis of verbal and nonverbal processes of marketing communication. The semiotics of marketing is a branch of applied semiotics, and an interdisciplinary field of research that investigates the signs, meanings, and communicative processes involved in marketing.

General surveys and discussions of semiotic research in marketing communication are Hetzel and Marion (1995), Mick (1997), Nöth (2000: 508–509, 531), Pasquier (1999), and Werner (2004). Volumes

Marketing is communication between marketers and consumers, with the purpose of directing the flow of products, services, information, ideas, and emotions from producers to consumers; it creates, satisfies, and reacts to demands, desires, and fashions of the marketplace in a process that involves the exchange of cultural, economic, and ideological values (Kotler, 1987: 3; Werner, 2004). The study of signs, meanings, and communication in the processes of marketing and the consumption of goods is a research field of applied semiotics, the 'semiotics of marketing' (*see* **Semiotics: History**).

Signs and Messages of the Marketplace

Marketing is not possible without language. The art of selling and creating involves a verbal rhetoric and a vocabulary of its own, and the word formation of brand names is a complex branch of linguistics with special relevance to marketing and economics in general (Piller, 2000). However, the marketplace is also the locus of countless nonverbal signs, whose study requires analytical tools of a general theory of signs. The gestures and facial expressions of the vendors and sales promoters are part of a nonverbal rhetoric of marketing; visual and musical messages support advertising campaigns in the media with nonverbal means; product and packaging design makes the object of exchange a material message, whose sender is the marketer and whose receiver is the consumer (Fritz, 1994; Nöth, 1998); logos and trade marks are indices both of a brand image and of corporate identities that contribute to the easy identification of the product in the multitude of goods available in the marketplace (Semprini, 1992; Gallert, 1998); and facts and myths concerning the utility and quality of the product, propagated by advertising campaigns, create a brand image that results in a complex semantics of goods (Aronoff, 1985). The marketplace is a stage of nonverbal communication, a communicative space where marketers and consumers meet to exchange goods, ideas, and values; it is everywhere in consumer societies, at home (mail, newspaper, telephone, television), in the street (machines, street vendors), at the local supermarket, the shopping mall, the industrial fair, the office, or on the World Wide Web.

Survey of Semiotic Approaches to Marketing

Semiotics, the general study of signs and sign processes, has provided analytical tools for the analysis of verbal and nonverbal processes of marketing communication. The semiotics of marketing is a branch of applied semiotics, and an interdisciplinary field of research that investigates the signs, meanings, and communicative processes involved in marketing.

General surveys and discussions of semiotic research in marketing communication are Hetzel and Marion (1995), Mick (1997), Nöth (2000: 508–509, 531), Pasquier (1999), and Werner (2004). Volumes

with collections of articles on the topic are Umiker-Sebeok, ed. (1987), and Larsen *et al*. (1991). Monographs dedicated to the topic are Floch (1990), Semprini (1992), Pasquier (1999), and Werner (1999). Special issues of journals on semiotic approaches to marketing are *International Journal of Research in Marketing 4(1–2)* (1988), *Quaderni di ricerche semiotiche 1(2)* (1987), and *Semiotic Inquiry 8(3)* (1988).

Closely related to the semiotics of marketing are three research fields of economics, which aim to interpret the flow of goods and services from producers to consumers. This is not as a process of production and distribution to satisfy consumer needs, but as an exchange of symbols between senders and receivers: the theory of symbolic consumption (Levy, 1959, 1978), consumer aesthetics (Hirschman and Holbrook, eds., 1981), and the semiotics of consumer behavior (Holbrook and Hirschman, 1993; Lambkin *et al*., 1998).

Verbal Exchange and the Exchange of Goods

There are differences and analogies between the flow of words in a dialogue and the flow of goods from producers to consumers in return for the flow of money in the opposite direction. Words and sentences in a dialogic exchange are immaterial, whereas goods and money in economic exchange evince materiality. Furthermore, the participants in a dialogue speak one and the same language, while producers and consumers of commodities speak and reply in two 'languages,' those of goods and of money (Coulmas, 1992). Semiotic features in common are that both words and goods are signs and constitute systems of values (Nöth, 1996).

Karl Bühler discussed "the exchange of goods" as "the counterpart of sign circulation" and described goods as signs with "symbolic values" (1934: 60–61). His focus was on trademarked goods, which evince two further parallels with words: conventionality and type-token structure. The conventionality of trademarked goods guarantees the sameness of their values in marketing and consumption. A product with a trademark, just like a spoken word of a given language, is a token of a more general semiotic type, namely its brand. According to Bühler, one of the differences between verbal signs and goods is their material quality. While material sameness is decisive for the value and the identification of a trademarked product, words are relatively flexible as to their phonetic realization, since they allow for much variation in voice, tone, and articulation.

Verbal Signs, Goods as Signs, and the Marketplace as a Sign System

Karl Marx set up the following parallels between goods and language signs: "Value . . . converts every product into a social hieroglyphic. Later on, we try to decipher the hieroglyphic, to get behind the secret of our own social products; for to stamp an object of utility as a value, is just as much a social product as language" (1867: 79) (*see* **Marxist Theories of Language**).

F. de Saussure, extending the analogy between words and goods to the level of the systems, argued that linguistics and economics are both "concerned with a *system for equating things of different orders* – labor and wages in one and a signified and signifier in the other" (1915: 79). In a comparison between the value of a loaf of bread worth five francs and the value of a word in a language, Saussure concludes (1915: 115) that both goods and words are signs displaying relations of similarity and dissimilarity within the systems to which they belong (*see* **Saussure, Ferdinand (-Mongin) de (1857–1913)**). Both consist of signifiers and signifieds, which are dissimilar; the loaf of bread's use value is dissimilar to its monetary *exchange value*, and a word is dissimilar to its meaning. At the same time, there are relationships of equivalence. In the system of economic objects, all goods of the same monetary exchange value are equivalent in this respect, just as verbal synonyms are equivalent to their semantic value or word categories to their syntactic value. Like the phonemes and words of a language, the goods of the marketplace form not only a system of paradigmatic relationships, which consists of their structures of equivalence, but also a system of syntagmatic relationships. The order and arrangement of food products in a supermarket or on a dinner table, the furniture in a living room, or clothes worn according to the rules of culture and fashion testify to a syntax of possible and excluded combinations of goods in everyday life.

Like words, goods are polysemic signs associated with a plurality of meanings not inherent in the goods themselves but generated in the marketplace. Products not only denote their use and exchange values, but also connote sociocultural, aesthetic, emotional, or mythical meanings (Nöth, 1998). The semiotic system of goods and services is a system of differences par excellence, since the discourse of the marketers tends to maximize the differences and minimize the similarities between the products in their attempts at making their offerings appear unique.

Self-Referential Words and Goods

Words refer to objects (their referents) just as goods refer to their practical utility and the needs they may satisfy (their *use value*). As such, both kinds of signs have reference to something else not inherent in themselves. In poetry and art, signs become self-referential when their purpose is no longer to convey a message but to communicate words as words (pure play of sounds) or visual forms as pure forms. It is a characteristic of affluent societies that the messages of the marketplace can become self-referential, too. Goods that do not satisfy needs or fulfill a practical purpose, such as gadgets or objects of fashion and luxury, are self-referential signs whose value exists only within the system created by the market. Consumers buy such goods not because they need or enjoy them, but because the market dictates their value and prescribes their purchase as a necessity.

The semiotic implications of affluent markets determined by such principles of economic self-reference have been the topic of the ideological critique of Baudrillard, which culminated in the argument that goods under such circumstances are signs whose signified is abolished in favor of a pure "play of signifiers" in which "the signifier becomes its own referent and the use value of the sign disappears to the benefit of its . . . exchange value alone. The sign no longer designates anything at all. It approaches its true structural limit which is to refer back only to other signs" (1973: 127–128). Irrespective of their use value, goods whose brand connotes nothing but status, prestige, or fashion, are signs that have become mutually exchangeable according to Baudrillard (1972: 64): "Dissociated from its use value, the object can now just as easily be a vase or a refrigerator, or, for that matter, a whoopee cushion. Properly speaking, it has no more existence than a phoneme has an absolute meaning in linguistics .... It finds meaning . . . in difference," in a "code of significations." With this ideological critique of a consumer society in which the use value of objects is no longer determined by the consumers' needs, but by the tyranny of the market and a semiotic system that produces needs which are only needs of the market itself, goods are no longer true signs, but simulations of a sign relation in which the signified is "abolished in favor of the sole profit of the play of signifiers." In the end, "the signifier becomes its own referent, and the use value of the sign disappears leaving the benefit of its commutation and exchange value alone. The sign no longer designates anything at all. It approaches its true structural limit which is to refer back only to other signs" (Baudrillard, 1973: 127–128).

Mark-up Languages: Speech

J Kusnitz, IBM Almaden Research Center, San Jose, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Until fairly recently, the web has primarily delivered information and services using visual interfaces, on computers equipped with displays, keyboards, and pointing devices. The web revolution had largely bypassed the huge market of customers of information and services represented by the worldwide installed base of telephones for which voice input and audio output provided the primary means of interaction.

VoiceXML 2.0 [VXML2], a standard recently released by the W3C [W3C], is helping change that. Building on the market begun in 1999 by the VoiceXML Forum's VoiceXML 1.0 specification [VXML1], VoiceXML 2.0 and several complementary standards are changing the way we interact with voice services and applications by simplifying the way these services and applications are built.

VoiceXML is an XML-based [XML] language, designed to be used on the Web. As such, it inherits several key features common to all XML languages:

- It leverages existing Web protocols such as HTTP to access remote resources.
- Any tool that is able to read or write XML documents can read and write a VoiceXML document.
- Other XML documents can be embedded in VoiceXML documents and fragments; similarly, VoiceXML documents can embed other XML documents and fragments. This the case with SRGS and SSML, which are described later.

As mentioned above, VoiceXML 2.0 is one in a number of standards that the W3C Voice Browser Working Group is defining to enable the development of conversational voice applications. The specifications making up the Speech Interaction Framework are the following:

- Speech Recognition Grammar Specification 1.0 [SRGS]
- Speech Synthesis Markup Language 1.0 [SSML]
- Semantic Interpretation for Speech Recognition 1.0 [SISR]
- Call Control Markup Language 1.0 [CCXML].

This article provides a short introduction to VoiceXML, as well as SRGS, SSML, and SISR, for building conversational web applications. CCXML is an XML-based language exposing telephony and call control functionality for such applications as conference call bridges and call routing. CCXML, however, is beyond the scope of this article.

Building Conversational Applications using VoiceXML

Menu Element

Most VoiceXML dialogues are built from one of two elements. The first of these is the <menu> element. A VoiceXML menu behaves much like a collection of HTML links.

A VoiceXML menu has a <prompt>, which contains SSML content, and one or more choices, each identified by a <choice> tag. Each choice consists of a phrase indicating what the user can say, as well as a link to the next VoiceXML document to be executed.

Consider this <menu> example:

```
<vxml version = "2.0" xmlns = "http://www.w3.org/2001/
  vxml">

  <menu>
    <prompt> Say one of: <enumerate/></
  prompt>
    <choice next = "http://www.example.com/
  sports.vxml">
      Sports scores
    </choice>
    <choice next = "http://www.example.com/
  weather.vxml">
      Weather information
    </choice>
    <choice next = "#login">
      Log in
    </choice>
  </menu>

</vxml>
```

Marr, Mikolai Jakovlevich (1864–1934)

V M Du Feu

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 5, p. 2388, © 1994, Elsevier Ltd.

Marr was born in Kutaisi, a small town on the Black Sea coast in Trans-Caucasia. His father was a Scotsman who died (reputedly at the age of 95) when Nikolai was eight years old; his mother was Georgian. He studied at the local grammar school, then went on to do oriental languages at St Petersburg; this included Turkic, Semitic, and Indo–Iranian. In 1891 he obtained a university appointment, and by 1912 was a member of the Academy.

His great service to Armenian and Georgian linguistics was the series of texts and accounts of research published between 1900 and 1915. His disservice – in the eyes of most linguists – lay in his attempts, especially from 1908 onward, to prove a genetic relationship between the Semitic languages and Georgian, and to group them under the term 'Japhetic.' Next he envisaged Japhetic as a stage not only in the early linguistic map around the Mediterranean, where a pre-Indo–European Pelasgian substratum had been mooted ever since the mid-19th century, but also in the ontogeny of language, and he sought 'primeval' forms in Japhetic, arriving eventually (1926) at just four syllables – *sal, ber, yon, rosh*. Human language he saw developing from these elements by stages ('stadia') which were provoked by economic changes. The notion of 'stadiality' was taken up by Stalin, and Marrism became part of Marxism in the Soviet Union in 1929. It remained the official line until Stalin's denunciation of it in 1950. By this time Marr had been dead for 16 years.

The 20 years of official Marrism led on the positive side to a great deal of work on Caucasian, Turkic, and Paleo-Asiatic languages which had hitherto been little studied and often had no written forms. The encouragement of minority languages had been part of Lenin's platform, so Marr's wide-flung interests fitted the bill. However, on the negative side, because of the strongly political nature of the official support, Marrism virtually cut Soviet linguists off from main linguistic developments in Western Europe and the United States, and even led to the 'disappearance' of some of them. Since it was also the framework of the linguistic formation of some generations of scholars, Marrism might be said to have laid the foundations of the (granted more scientific looking) Nostratic theory linking Dravidian, Hamitic, Altaic, Anatolian, Tungusian, Akkadian, etc., as providing evidence of a widespread proto-language, a notion propagated by the late Illich-Svitich in the 1970s, and supported by the eminent I. I. Ivanov in the 1980s. This current Nostratic theory may be dismissed, but its methods, *rapprochements* on the basis of very thin evidence, are very much in the negative line of Marr's work. Whatever the ultimate judgment of a history of linguistics on the work of N. J. Marr, an appreciation of the results of the dominance of Marrism between 1930 and 1950 is vital to the understanding of subsequent attitudes among many Russian and former Soviet linguists.

Marshall Islands: Language Situation

B Palmer, University of Surrey, Guildford, UK

© 2006 Elsevier Ltd. All rights reserved.

The Republic of the Marshall Islands is a Pacific state comprising 29 atolls and five tiny islands in two parallel chains running northwest to southeast just north of the equator in Micronesia. The total land area is about 180 square kilometers (69 square miles), scattered across about 750 000 square kilometers (289 575 square miles) of ocean.

The Marshall Islands were initially settled more than 2000 years ago by Austronesian speakers. The Marshallese remained skilled ocean voyagers, and there is evidence of regular contact with other Pacific groups. However, the Marshallese remained isolated from Western influence until the arrival of whalers and missionaries during the 19th century. A German

Marshall Islands: Language Situation

B Palmer, University of Surrey, Guildford, UK

© 2006 Elsevier Ltd. All rights reserved.

The Republic of the Marshall Islands is a Pacific state comprising 29 atolls and five tiny islands in two parallel chains running northwest to southeast just north of the equator in Micronesia. The total land area is about 180 square kilometers (69 square miles), scattered across about 750 000 square kilometers (289 575 square miles) of ocean.

The Marshall Islands were initially settled more than 2000 years ago by Austronesian speakers. The Marshallese remained skilled ocean voyagers, and there is evidence of regular contact with other Pacific groups. However, the Marshallese remained isolated from Western influence until the arrival of whalers and missionaries during the 19th century. A German

protectorate from 1885 until 1914, the Marshall Islands was a Japanese colony until 1944, when it was taken over by the United States until full independence in 1986. Best known as the site of U.S. nuclear testing at Bikini atoll, the Marshall Islands retains close ties with the United States, and Kwajalein atoll remains a missile testing range. Two-thirds of the population live in the national capital on Majuro atoll and on Ebeye, a shanty-covered islet housing workers at the Kwajalein range.

The country is home to one indigenous language spoken by most of its 57 000 inhabitants. Marshallese is a Nuclear Micronesian language within the Oceanic branch of Austronesian, most closely related to Ponapean (Pohnpeian), Kosraean, and Kiribati. The linguistic origin of the Micronesian grouping is not certain but is likely to have been the Solomon Islands or Vanuatu. Marshallese has two major dialects, one associated with the eastern Rātak ('sunrise') Chain, the other with the western Rälik ('sunset') Chain. Within each a few subdialects exist, particularly on Ujelang in Rälik and Mejit in Rātak. The Rātak dialect has slightly higher prestige because of early Bible translations, but a koine is emerging in Majuro and Ebeye. Despite the vast distances, dialect divergence is small and limited to phonology and lexicon. No grammatical differences have been reported. The language is also spoken by a migrant community on Nauru.

German and Japanese had negligible lasting effects on Marshallese. However, the English language and American culture have had a substantial impact on Marshallese life. Many cultural practices have been abandoned and the associated terminology largely lost, and several ritual languages are no longer used. Marshallese and English are joint official languages. Marshallese is the language of government, and a language commission was established by legislation in 1983 to preserve, develop, and encourage the use of Marshallese. However, English is favored by the elite and educated. Marshallese is the language of education at the primary level, and English is used at the secondary level.

Marstrander, Carl J. S. (1883–1965)

D Haug, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

The Norwegian Celtologist and Runologist Carl Marstrander studied Classical Philology and Indo-European languages at the University of Kristiania (now Oslo) until he got a scholarship to go to Ireland in 1907. From 1908 he was a research fellow in Indo-European linguistics at the University of Kristiania, and in 1910–1913 he was Professor of Celtology and Comparative Linguistics at the School of Irish Learning in Dublin. From 1913 until he retired he was professor of Celtic languages at the University of Kristiania/Oslo.

Marstrander conducted many field studies in different Celtic-speaking areas: Blasket (1907), Bretagne (1919–1922), and Manx (1929, 1932), and he led a linguistic survey of the Gaelic dialects of Scotland from 1937 on. But although he had a lively interest in the living Celtic languages, little of this material was published; his published work mostly concerns older stages of Celtic. During his time in Dublin he edited the first fascicle of the Royal Irish Academy's *Dictionary of the Irish language based mainly on old and middle Irish materials*. He also approached Celtic from a comparative Indo-European point of view, as in his work *Observations sur les presents indo-européennes à nasale infixée en celtique* (Christiania, 1924), and he worked on other Indo-European languages: in his *Caractère indo-européen de la langue Hittite* (Christiania, 1919), he was among the first Indo-Europeanists to accept Hrozný's decipherment of Hittite and the conclusion that the language was Indo-European.

Another main interest was the study of the interactions between Celtic-speaking areas and the Kingdom of Norway in the Middle Ages as witnessed by his *Bidrag til det norske sprogs historie i Irland* ('Contributions to the history of the Norwegian language

Marstrander, Carl J. S. (1883–1965)

D Haug, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

The Norwegian Celtologist and Runologist Carl Marstrander studied Classical Philology and Indo-European languages at the University of Kristiania (now Oslo) until he got a scholarship to go to Ireland in 1907. From 1908 he was a research fellow in Indo-European linguistics at the University of Kristiania, and in 1910–1913 he was Professor of Celtology and Comparative Linguistics at the School of Irish Learning in Dublin. From 1913 until he retired he was professor of Celtic languages at the University of Kristiania/Oslo.

Marstrander conducted many field studies in different Celtic-speaking areas: Blasket (1907), Bretagne (1919–1922), and Manx (1929, 1932), and he led a linguistic survey of the Gaelic dialects of Scotland from 1937 on. But although he had a lively interest in the living Celtic languages, little of this material was published; his published work mostly concerns older stages of Celtic. During his time in Dublin he edited the first fascicle of the Royal Irish Academy's *Dictionary of the Irish language based mainly on old and middle Irish materials*. He also approached Celtic from a comparative Indo-European point of view, as in his work *Observations sur les presents indo-européennes à nasale infixée en celtique* (Christiania, 1924), and he worked on other Indo-European languages: in his *Caractère indo-européen de la langue Hittite* (Christiania, 1919), he was among the first Indo-Europeanists to accept Hrozný's decipherment of Hittite and the conclusion that the language was Indo-European.

Another main interest was the study of the interactions between Celtic-speaking areas and the Kingdom of Norway in the Middle Ages as witnessed by his *Bidrag til det norske sprogs historie i Irland* ('Contributions to the history of the Norwegian language

in Ireland', Kristiania, 1915) and by articles on Old Norse language and religion in Ireland and on the Isle of Man.

Outside the Celtic languages, his main interest lay in runology. He presented his theory on the origin of the runes from Italic and Celtic alphabets used in the Alp region in the last century B.C. and their names in the first volume of *Norsk Tidsskrift for Sprogvidenskap*, which he founded in 1928 and edited until his death, thus creating a publication channel for the increasing number of Norwegian linguists. In this forum and others he published numerous studies on different runic inscriptions and brought lasting contributions to the interpretation of many of them.

Martin of Dacia (d. 1304)

L Kaczmarek, Borgholzhausen, Germany

© 2006 Elsevier Ltd. All rights reserved.

Martin of Dacia (i.e., of Denmark, also known as Martinus de Dacia or Martinus Dacus in Latin and called Morten Mogensen in Danish) is one of the founders of speculative or modistic grammar. He taught grammatical and logical subjects in the Parisian arts faculty. At Paris he also held the title of Master of Theology. In the 1270s and 1280s, perhaps even earlier, in addition to his well-known and often-cited *Modi significandi* (edited in Roos, 1961: 1–118; French translation of sections 197–270 on syntactical matters in Rosier, 1982), he composed questions (*Quaestiones*) on the so-called Old Logic (*Logica vetus*) (edited in Roos, 1961), Porphyry (Roos, 1961: 119–152), Aristotle's Categories (153–231) and Interpretation (233–263), the *Liber sex principiorum* (265–315), and Boethius' commentary on the Topics (317–327).

From 1287–1288 to 1300, he served as chancellor to Erik VI Menved, king of Denmark, who had him made canon in Roskilde, Lund, and Slesvig, and was the king's candidate for the title of bishop of Roskilde, but did not succeed. Some sources attach him to the Dominican order. He died on August 10, 1304, and was buried at Notre Dame in Paris, where he also had held a canonry. His *Modi significandi*, which he wrote in reaction to Boethius of Dacia, were commented upon by the contemporary grammarians Gentile da Cingoli (cf. Marmo, 1994: 11, n. 41) and Michel de Marbais, among others (see Roos, 1961: xvii–xxi and Pinborg: 314–316).

Martin, Samuel (b. 1924)

M McCaskey, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Samuel E. Martin received the B.A. and M.A. degrees in Oriental languages from the University of California at Berkeley, and a Ph.D. in linguistics from Yale University. His dissertation, *The phonemic status of ancient Chinese vowels* (1949), was the first of a lifetime of studies of East Asian languages. Martin began teaching at Yale University in 1950, and continued as a Yale faculty member for more than half a century, with occasional periods of research and teaching at the University of Hawaii and other universities.

Martin has an impressive and prolific publication history, which began early in his career with a series of four studies of three east Asian languages. These works, *Morphophonemics of standard colloquial Japanese* (1952), *Honorific and familiar speech in Japanese* (1952), *Readings in contemporary Korean* (1952), and *The phonemes of ancient Chinese* (1953), all reflected expertise in the major languages of Northeast Asia. They also foretold Martin's lifelong interest in both theoretical and applied east Asian linguistics.

Martin's *Essential Japanese: an introduction to the standard colloquial language* (1954) and *Basic Japanese conversation dictionary* (1959) were the first practical Japanese language resources published in English after World War II. He also produced parallel practical Korean references, as well as the *Dagur Mongolian grammar, texts, and lexicon: based on the speech of Peter Onon* (1961). These, together with many other applied Japanese and Korean linguistic studies by Martin, served as essential east Asian language-learning tools for several generations of American students.

Over the course of his scholarly career, Martin also produced several books that have become standard references for English-speaking scholars of east Asia conducting original-language research. Martin combined his own expertise with the insights of highly educated informants and discussants, matching the best works in the original languages in depth, breadth, accuracy, and linguistic insight. Analyses were developed through extensive discussions with informants, and many points never touched upon before in English were explained with thoroughness and total authenticity, with freshly generated linguistic examples.

Martin's *The Japanese language through time* (1987) was a diachronic study of the Japanese language, primarily focused on phonological and etymological issues. In addition to providing theoretical reconstructions of ancient phonemic and phonetic features, tracing their development up to the present day, Martin also related these changes to parallel morphological transformations of verb and adjective inflections, and to the development of modern regional accents. Martin also discussed the work of traditional Japanese linguistic scholars, analyzing key citations from them. The product of a decade of research, this work of close to a thousand pages remains a unique and indispensable reference for Western linguistic historians interested in the Japanese language.

Martin also produced a pair of reference grammars, designed for English-speaking researchers in Korean and Japanese, which remain unsurpassed today. His *Reference grammar of Japanese* (First edn., 1975) focused for the most part on the modern language, though many points of classical grammar were dealt with as well. *A reference grammar of Korean: a complete guide to the grammar and history of the Korean language* (1992) dealt with both modern and historical grammar, and reflected four decades of research. Each reference grammar was over a thousand pages long, with copious illustrative examples and thorough indexing.

During his half century at Yale, Professor Martin has at different times served as chair of the Department of East and South Asian Languages and Literatures, and of the Department of Linguistics, reflecting his outstanding expertise in both areas. He subsequently became professor emeritus in both departments as well.

Martinet, André (1908–1999)

T P Górski, Uniwersytet Wrocławski, Wrocław, Poland

© 2006 Elsevier Ltd. All rights reserved.

André Martinet (1908–1999), French linguist, studied English in Paris (taking courses from J. Vendryes and A. Meillet) and Berlin, and lectured at the École Pratique des Hautes Études. After World War II, he worked as a professor at Columbia University in New York and in 1955 at the Sorbonne.

Martinet took great advantage of the Copenhagen Circle and the Prague Circle, especially the glossemantics of Hjemslev and the principles of phonology. In collaboration with Tesnière, Vendryes, and Benveniste, he devoted a great deal of time the publication of the works of the Prague Circle. Martinet's views, referred to as functional linguistics, dealt mainly with phonology, the relation of diachronic to the synchronic, and morphology. He distinguished two types of articulation of the linguistic sign (referred to as double articulation): monemes, i.e., the units of the first articulation that have a phonetic form and meaning (and at the same time being signs), and phonemes, i.e., units of differentiating function and carrying no meaning. For example: *I have two dogs and a cat* consists of seven monemes (*I/have/two/dogs /and/a /cat*, and phonemes as *h, v, t, w, d, g, s, c, t,* etc. He sees the double articulation as a peculiar feature of human language since it allows for creation of unlimited number of words as a result of a combination of a definite number of relevant segments of sounds. Every language has its own particular articulation (both of the utterance and its form): (French) *J'ai mal à la tête* = (Italian) *Mi duole il capo* (*Je, il capo* are subjects; but *mal* is a noun, *duole* is a verb).

Martinet saw linguistics (the study of *langage*) as a non-normative science in which phonic signs are regarded as signs that ensure communication between people. Since language is a tool of communication, it plays an important role in the social interactions of the particular nations and is peculiar to them, but, at the same time, it does not mirror reality. Every language has its own separate and determined set of experiences that differentiate its nomenclature: words such as *cheval, horse, Pferd* are built of the same letters of the alphabet, but differ in the phonetic structure (accent, place and manner of articulation of particular sounds, etc.). Thus, the experience is analyzed differently in different societies and given the form of monemes. Monemes are ultimately divided into distinctive elements: phonemes. Any sign can be called linguistic as long as it is characterized by double articulation and is phonically perceptible. The presence of these features becomes the basis that differentiates linguistic signs among languages. Such observation is also seen in the arbitrariness and conventionality of utterances. Learning a foreign language, in this view, is not giving new labels to objects the learner already knows, but analyzing the content of the linguistic utterances.

Phonemes, in Martinet's view, are discreet units of language in the sense that the number of phonemes in a language is definite. Alphabetic writing of languages, being a calque of phonemic distribution, preserved the discreetness: every letter is regarded as a representative of a definite number of sets; the clearer the utterance becomes, the easier the phonemes are identified. Thus, the discreet character of a phoneme is not affected by the change of context, or any external factors.

In his research, Martinet put great emphasis on the complex problem of identification of phonemes. He claimed that in case of consonant phonemes, the difference between bilabials /p/ and /b/ is that of vocality (p (−Voice), b (+Voice)), since both sounds are articulated identically. As a result, in his terminology, b is in contrast to p, a sonorant. In this way, Martinet proved that the same phonic production can represent different phonemes and two series of phonemes constitute a correlation (e.g., corresponding p – f – t – s – ʃ – k and b – v – d – z – ʒ – g). Phonemes are regarded as the indispensable elements of the function of language.

Considering their function in sentences, Martinet divided the monemes into three groups: autonomous, which may take various places in sentences (e.g., always, today, slowly); functional, when meaning, not the place, determines its function (e.g., in, on, at); and dependent, subordinated to is place (e.g., syntactically interchangeable subject and object in *The secretary doesn't like the manager* ≈ *The manager doesn't like the secretary*).

Martinet applied this distinction to all kinds of articulatory signs, not only to linguistic ones. On the basis of the achievements of information theory, he developed the idea of the linguistic change caused by the continuous conflict between the tendency to the maximal diversification of signs to increase informativity and the tendency to save the energy required to the articulation of the sign.

Martinet's research on diachronic phonology (he was the first to introduce the issue of analyzing the entire set of phonological systems) had an effect on the formulation of the phonological chain reaction. According to this theory, the changes in the articulation of consonants that cause the identification of two

different phonemes or the diversification of two different variants of the same phonemes may lead to changes in the articulation of vowels of the same syllable. Thus, a change of language is directed at obtaining the simplest structure of its elements. Martinet called the issue the articulatory and functional economy of language. Studies of language, both synchronic and diachronic, should reveal the way the language functions, how the language transforms human experience into linguistically significant units, and how humans utilize their articulatory organs to produce different sounds.

Martinique: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Officially called the Department of Martinique, this overseas territory of France is situated in the eastern Caribbean, in the Windward Islands, West Indies. The volcanic island was already inhabited by Carib Indians before Christopher Columbus landed in 1502, preceded by the Arawaks, who came to the island from South America. It was continuously settled by the French beginning in 1635 and annexed by France in 1674. The French brought in African slaves as sugar plantation workers and fought against the British in the short occupation by the latter in the early 19th century. The re-established French administration that followed this was economically based on sugar cane plantations and slavery, until the abolitionist movement brought an end to slavery in 1848. However, sugar continued to hold an important position in the economy. In 1946 Martinique became an overseas department of France. In 1958 the island opted for integrating with the mainland French community, and in 1974 it was assimilated as a region of France.

Martinique has a population of 429 510 (July 2004) and thus is considered overpopulated (its territory is 1101 sq km). The population is very diverse as a result of the mixing of different ethnic groups that inhabited it during history. Minorities include those of European, Asian Indian, Amerindian, Arab, and Chinese origin. French is the official language, but the local French-based creole or patois (Lesser Antillean Creole French) is more widely used among Martinican islanders. This creole grew out of the pidgin that early setters used to communicate with each other and shows substrate influence from African languages. The adult literacy level is 97.7%.

Marty, Anton (1847–1914)

S Watanabe, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Martin Anton Maurus Marty, philosopher of language, was born as the ninth child of eleven children of a shoemaker and sacristan named Jacob J. A. Marty in Schwyz, Switzerland. His elder brother, Alois Joseph, a Benedictine, became one of the founders of the Catholic University of America.

Marty studied philosophy and theology at a Catholic seminary in Mainz, Germany, where he published a prize-winning thick thesis (about 300 pages) titled *Die Lehre des hl. Thomas über die Abstraktion der übersinnlichen Ideen aus den sinnlichen Bildern nebst Darstellung und Kritik der übrigen Erkenntnistheorien*. Scarcely 20 years old at that time, he already showed the strong influence he had received from Franz Brentano's *Von der mannigfachen Bedeutung des Seienden nach Aristoteles*. He came to be Brentano's student at Würzburg University and was greatly influenced by his mentor's empirical psychology. In 1869 he started teaching at the Catholic lyceum in Schwyz as professor of philosophy and received ordination of a higher degree.

When Brentano, a Catholic priest, left his church in protest against the promulgation of the infallibility of the popes as a dogma, Marty also retired from his church. After leaving Switzerland, he studied at Göttingen University with Hermann Lotze, a physical-anthropological philosopher, as his mentor, took his doctor's degree with a dissertation titled 'Über den Ursprung der Sprache' and was appointed professor of philosophy at a newly-established university at Czernowitz (now Chernovtsy in Ukraine) in 1875.

Owing apparently to his thesis *Die Frage nach der geschichtlichen Entwickelung des Farbensines* (1879), he was called to the German University of Prague in 1880 and devoted himself to exploring scientifically the new field of linguistic philosophy, which he regarded as an integral part of linguistics until he retired in 1913. He was appointed dean of the Department of Philosophy, Vienna University, in 1890. Though he suffered from depression in his later years, he continued to finish his lifework *Untersuchungen zur Grundlegung der allgemeinen Grammatik und Sprachphilosophie* (Vol. I, 1908).

His collected works were edited by Eisenmeier, Kostil and Kraus as *Gesammelte Schriften* (2 vols. 1916, 1920), which did not include his thesis published in book form. Otto Funke, professor at Bern University, who further developed Marty's ideas, edited Marty's unpublished works as *Nachgelassene Schriften* (Bern, 1940–1950), which include important works such as 'Über Prinzipenfragen der Sprachwissenschaft,' 'Über Wert und Methode einer beschreibenden Bedeutungslehre,' 'Von den semasiologischen Einheiten und ihren Untergruppen,' and 'Von den logisch nicht begründeten synsemantischen Zeichen.' His biography *Anton Marty: sein Leben und seine Werke* (Halle, 1916) was written by Oskar Kraus.

Marty's significance for the history of linguistics chiefly lies in his cogent argumentation against the nativistic parallelism between mind and language, which was introduced into linguistics by Wilhelm von Humboldt and reinforced by Heyman Steinthal and Wilhelm Wundt. Marty's idea concerning *innere Sprachform* was empirical-teleological. His influence was perceptively great in Japan in the 1940s, with the respect that Funke, philologist and Marty's expounder, is highly respected among English philologists there.

Marxist Theories of Language

G Mininni, University of Bari, Bari, Italy

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 5, pp. 2390–2393, © 1994, Elsevier Ltd.

The hinges of a Marxist consideration concern the links binding the language to the structure of society, to models of material praxis, and to forms of ideology. An evaluation of the relationship between Marxism and the sciences of language coincides with the overall judgment expressed by many scholars on the historical experience of the so-called 'real socialism': the questions on the agenda are relevant and unavoidable, but the answers given are, on the whole, misleading or disappointing. The questions posed by Marxism as an interpretive methodology of social relationships may be worded as follows: which linguistic arguments prove that 'man is the sum of social relationships?' How are the different systems of beliefs, socially shared knowledge, cultural values, and rules of a human community continuously rebuilt in his language? How do the ideal–typical

Marty, Anton (1847–1914)

Martin Anton Maurus Marty, philosopher of language, was born as the ninth child of eleven children of a shoemaker and sacristan named Jacob J. A. Marty in Schwyz, Switzerland. His elder brother, Alois Joseph, a Benedictine, became one of the founders of the Catholic University of America.

Marty studied philosophy and theology at a Catholic seminary in Mainz, Germany, where he published a prize-winning thick thesis (about 300 pages) titled *Die Lehre des hl. Thomas über die Abstraktion der übersinnlichen Ideen aus den sinnlichen Bildern nebst Darstellung und Kritik der übrigen Erkenntnistheorien*. Scarcely 20 years old at that time, he already showed the strong influence he had received from Franz Brentano's *Von der mannigfachen Bedeutung des Seienden nach Aristoteles*. He came to be Brentano's student at Würzburg University and was greatly influenced by his mentor's empirical psychology. In 1869 he started teaching at the Catholic lyceum in Schwyz as professor of philosophy and received ordination of a higher degree.

When Brentano, a Catholic priest, left his church in protest against the promulgation of the infallibility of the popes as a dogma, Marty also retired from his church. After leaving Switzerland, he studied at Göttingen University with Hermann Lotze, a physical-anthropological philosopher, as his mentor, took his doctor's degree with a dissertation titled 'Über den Ursprung der Sprache' and was appointed professor of philosophy at a newly-established university at Czernowitz (now Chernovtsy in Ukraine) in 1875.

Owing apparently to his thesis *Die Frage nach der geschichtlichen Entwickelung des Farbensines* (1879), he was called to the German University of Prague in 1880 and devoted himself to exploring scientifically the new field of linguistic philosophy, which he regarded as an integral part of linguistics until he retired in 1913. He was appointed dean of the Department of Philosophy, Vienna University, in 1890. Though he suffered from depression in his later years, he continued to finish his lifework *Untersuchungen zur Grundlegung der allgemeinen Grammatik und Sprachphilosophie* (Vol. I, 1908).

His collected works were edited by Eisenmeier, Kostil and Kraus as *Gesammelte Schriften* (2 vols. 1916, 1920), which did not include his thesis published in book form. Otto Funke, professor at Bern University, who further developed Marty's ideas, edited Marty's unpublished works as *Nachgelassene Schriften* (Bern, 1940–1950), which include important works such as 'Über Prinzipenfragen der Sprachwissenschaft,' 'Über Wert und Methode einer beschreibenden Bedeutungslehre,' 'Von den semasiologischen Einheiten und ihren Untergruppen,' and 'Von den logisch nicht begründeten synsemantischen Zeichen.' His biography *Anton Marty: sein Leben und seine Werke* (Halle, 1916) was written by Oskar Kraus.

Marty's significance for the history of linguistics chiefly lies in his cogent argumentation against the nativistic parallelism between mind and language, which was introduced into linguistics by Wilhelm von Humboldt and reinforced by Heyman Steinthal and Wilhelm Wundt. Marty's idea concerning *innere Sprachform* was empirical-teleological. His influence was perceptively great in Japan in the 1940s, with the respect that Funke, philologist and Marty's expounder, is highly respected among English philologists there.

Marxist Theories of Language

G Mininni, University of Bari, Bari, Italy

The hinges of a Marxist consideration concern the links binding the language to the structure of society, to models of material praxis, and to forms of ideology. An evaluation of the relationship between Marxism and the sciences of language coincides with the overall judgment expressed by many scholars on the historical experience of the so-called 'real socialism': the questions on the agenda are relevant and unavoidable, but the answers given are, on the whole, misleading or disappointing. The questions posed by Marxism as an interpretive methodology of social relationships may be worded as follows: which linguistic arguments prove that 'man is the sum of social relationships?' How are the different systems of beliefs, socially shared knowledge, cultural values, and rules of a human community continuously rebuilt in his language? How do the ideal–typical

needs for mutual understanding and the real contingencies of differentiation and social struggle weave together in the language? These queries question all the symbolic articulations connected with the difference between manual labor and intellectual work.

Looking for a 'True' Marxism in Linguistics

What is the meaning of 'being a Marxist in linguistics?' First of all, it must be stressed that from a methodological point of view, it is not a question of applying Marxism to linguistics (Ponzio, 1989), as such an approach carries the idea of a 'will of power,' which is not acceptable for cultural practices guided by the paradigm of the search for a historical, consensual truth. Any attempt at a mere external application legitimates a defense mechanism aiming at protecting the autonomy of language science against the obtrusiveness of ideological knowledge. To adhere to a Marxist theory of the language does not mean to draw the proposals of a linguistic explanation from the dogmas of social philosophy, but to identify a route of interpenetration between the problems posed by linguistic practice (or reflection) and the possibilities of an unbiased analysis of the same at a social level, just like the one Marx carried out to explain how the capitalist economy of his time worked.

Classics' Indications

The hypothesis of a direct accessibility between Marxism and language sciences may seem surprising when one considers that the assertions concerning language are poor and fragmentary in the classical literature of Marxism. Some passages from the *German ideology* are extremely enlightening, especially those where Marx and Engels (1970) explain that language originated from the need for relationships with others, and is the matter that from the beginning 'contaminates' the spirituality of a 'real, practical conscience,' which is typical of man. Other noteworthy references can be found in the section about *Nature's dialectic*; here Engels develops Darwin's theme of the ape's humanization processes and suggests the existence of a strict connection between language and work. Of course, from an early date (Lafargue, 1894), scholars' attention was attracted by the possibility of identifying a class-prejudiced characterization both in the use of language and in the process of its historical evolution (*see* **Class Language**). This assumption does not justify in the least the absurd contraposition of a 'socialist' or 'revolutionary linguistics' to a 'capitalist' or 'reactionary one,' which would necessarily occur if Marxist theoretical and ideological principles were schematically applied in a scientific investigation of linguistic problems.

Scylla and Charybdis in Marxist Linguistics

A subtle plot of historical and political conditions led Joseph V. Stalin to denounce the fact that Mikolai J. Marr (*see* **Marr, Mikolai Jakovlevich (1864–1934)**) (the recognized spokesman of Marxist theory in linguistics until then) had incurred such an aberration in his doctrine, as he had reconciled his own monogenetic (or Japhetic) hypothesis of language with assertions about its superstructural and class-prejudiced nature. The great normalizer of the Soviet State often intervened in the linguists' debate published in *Pravda* (summer 1950), and – as an expert on Marxism, not on glottology – he presumed to outline the correct picture of a Marxist interpretation for linguistic questions. Stalin's position – which seems to be supported by common sense and is consistent with the scientific programs of Saussure's structuralism and Durkheim's sociology – turns out to be fundamentally incorrect both in its method and in substance, although it is absolutely justified by virtue of a certain sociolinguistic policy. As a matter of fact, on the one hand, the pretension to solve a scientific debate by a substantial appeal to authority appears unacceptable; on the other hand, the rebuttal of Marr's thesis is carried out with the help of trivializing arguments. However, from the point of view of the history of thought, Stalin's intervention is an affirmation and, at the same time, a denial of a Marxist theory on language. It is an affirmation because it demonstrates *de facto* that any theoretical language elaboration is bound by reasons of social and political practice. Language sciences, too, obey precise constraints deriving from the development of human relationships and draw inspiration from the ideological climate in which a society lives. Actually Stalin's concern to preserve languages conceals the 'sovietization' process imposed on the different nationalities gathered in the former USSR, and aims at defusing social conflicts. But Stalin's position patently clashes with that dimension of Marxist theory, so it necessarily adheres to a 'critical linguistics,' that is to say, a linguistics that tries to unveil the dominant mechanisms operating in communicative practices (*see* **Critical Discourse Analysis**). For a number of reasons, Stalin could not adopt such a view, and in order to avoid the problems that Marr had reasonably posed but incorrectly solved (Borbé, 1974), he takes refuge in an attitude of denial: as a language system has its own autonomous organization and is an instrument of national identification, language is not a superstructure and does not have a class character, so Marrism is not the equivalent of Marxism in linguistics. Stalin's position is not only mistaken, as he commits the 'minimalist error' (Mey, 1978) of considering language as a mere by-product of the cultural

life of a nation, but it is also responsible for putting an end to the debate on the potential of Marxism in linguistics, through its own mystification (Marcellesi and Gardin, 1974).

Language Sciences and Critique of Ideologies

If we escape both monsters of Marrism and Stalinism, are there other implemented models of interpenetration or mutual control between the social theory of Marxism and linguistic questions?

'Bakhtin's Circle'

In fact, an authentically Marxist position in the language sciences is worked out in the postrevolution decade in Russia by the so-called 'Leningrad School.' Michail M. Bakhtin (*see* **Bakhtin, Mikhail Mikhailovich (1895–1975)**), Valentin N. Voloshinov (*see* **Voloshinov, V. N. (ca. 1884/5–1936)**), and Pavel N. Medvedev tried to develop a semiotic theory of culture based on Marxist principles. Their conceptual pattern set three interpretative routes: decoding psychic processes both historically and socially; exploring the polyphonic dialogics intrinsic in a language; identifying the sociological constraints of a literary text. The Marxist relevance criterion of such an approach is the criticism of the forms of ideology and the way ideology works. In Voloshinov's opinion (1973), a Marxist conception of the problems posed by language philosophy is warranted by the need to explore the sign nature of ideological phenomena. As a result, the study of the ideologies embodied in the ethical, religious, juridical, political, and literary institutions of a society must be based on an explanation of the principles regulating their constitutive elements: i.e., signs. The identification of the ideological sphere with semiotics enables us to explain the formation of an individual conscience as a socio-ideological phenomenon; one must therefore imagine an unseizable dialectic interaction between the mind's working and the activation of sign-ideological systems (*see* **Dialogism, Bakhtinian**). The specifically psychological aspects of such an explanatory route were developed by Lev S. Vygotsky (*see* **Vygotskii, Lev Semenovich (1896–1934)**); his theory advocated that superior psychic processes (memory, language, will, etc.) are interiorizations of social interactions mediated by signs. To explain the connection between language and ideology, Voloshinov resorted to a meta-procedural strategy: he showed which ideologies are carried by linguists. Two macrotrends are therefore identified in the study of language, which appear as epistemological constants and are still in force: individualist subjectivism (from Humboldt to Croce and Vossler) and abstract objectivism (which was exemplarily represented by Saussure) (*see* **Saussure, Ferdinand (-Mongin) de (1857–1913)**). Voloshinov demonstrated that the Marxist point of view calls for an analysis of the socioideological material 'molded' by verbal interaction in order to rebut both the unsubstantiality of individual creativity in linguistic expression and the narrow-mindedness of a superindividual system of rules escaping the manifold pressures of language usage.

Social Cognition and Linguistic Praxis

The debate interrupted by Stalin and the programs started by the 'Leningrad School' were reconsidered in the 1960s both by Soviet scholars who were interested in giving a historical and materialist direction to semiotic structuralism (Reznikov, 1964) and by other scholars working in the field of social criticism in the capitalist West (Cornforth, 1967). An interesting bridge between these two perspectives had been sketched in Italy by Antonio Gramsci's brilliant intuitions and was later consolidated in Poland by Adam Schaff (1967). The need for a 'Marxist linguistics' was set by the Polish philosopher in the sphere of a knowledge theory beyond the opposite extremes of mechanistic materialism and subjective idealism. According to Schaff, a Marxist theory emphasizes the role of mediating procedure that language plays between what is subjective and objective, mental and social, biological and cultural. This theory acts as a central support for a conception of man as the being who is responsible for the creation of his own cognitive and relational models. Even if some differences can be found from the point of view of inner logic as well as on the level of phylogenetic and ontogenetic acquisition, the process of 'thinking–speaking' is substantially unitary, as cognition is an effect of social praxis and communicative relations are full of cognitive contents. This dialectic unity enables us to reject both the reflex theory suggested by a naïve materialism and the theory of significant systems autonomy, proposed by some updated versions of idealism. Furthermore, Schaff's Marxist language theory aims at being immediately employed in the practical questions weighing on the decision-making ability of a human person as an actor and a maker of his or her social world. On this subject, Schaff also considers a social categorization process that emphasizes the connection between ideology and language, that is, 'thinking–speaking by stereotypes.' The resort to stereotype and to prejudice gives emphasis to the fact that as the relationship between the individual mind and reality is mediated by the sphere of meanings, the workings of the mind itself are influenced

by historical and social conditionings. Stereotypes reveal the real control that social groups have over the contents and processes of individual thought. Schaff's pragmatic point of view allowed him to give stereotypes of the sociointegrative and defense functions that make the workings of the mind compatible with the political structure of society. Similar conclusions are drawn by all those currents of sociolinguistics and pragmalinguistics that wonder about the connections between the conscience of sociality carried by the language and the limits of what the historical conditions of praxis allow human subjects to mean when they are diversified by factors such as age, sex, culture, class, degree of social control, etc. Some theories within 'social linguistics' are marked by an implicit adhesion to a Marxian inspiration, such as 'praxematics,' coming from Lafont's school or Mey's pragmatic approach. Lafont (1978) works out a linguistics focused on the 'praxeme': this is an instrument for the production of sense in speech and, at the same time, a unit of analysis in the relation between the language user and the practical social conditions that make it possible for the uses of linguistic varieties to clash. In outlining the basic question '*Whose language*?,' Mey (1985) makes a constant, critical comparison between the categories obtainable from analysis of industrial society (such as production, oppression, and manipulation) and the instruments of linguistic analysis. According to Mey, the Marxian inspiration in sociolinguistics lies in the need for a theory that can explain the intricate relationship between language as a sociocultural product and the forms of the overall reproduction of a society. The solution he proposes entrusts pragmatics, as the theory of linguistic use, with the task of explaining the various 'wording' possibilities connected with the clashing nature of groups, with different approaches to knowledge and with different power distributions.

Sign Systems and Social Reproduction

The principles of historical–dialectical materialism imply that language is interpreted by abstractions that are in turn determined by the sum of practices regulating man's 'organic exchange' with nature, bearing in mind the often distorted representations imposed by the historical limits within which man is obliged to live his social relationships (Erckenbrecht, 1973). The Marxist idea of language aims at specifying the features of the production of sense carried out by man in the present circumstances of his history and, therefore, at identifying the role of sign systems within the process of 'social reproduction' as a whole. This category indicates the totality of techniques and procedures through which human groups perpetuate their presence in the world. In this perspective, Ferruccio Rossi-Landi's tentatively investigated connection between language and work is justified (1983). At first sight, Rossi-Landi seems to exaggerate when he applies the Marxian labor theory of value to the field of language and to other nonverbal forms of human communication. Indeed, the most important thing is the epistemological and methodological indication of the need for passing from the surface level of exchange and/or the sign market to the underlying level of social labor that is implicit in cultural signification and communication processes. This change of focus makes it possible to criticize the dichotomy traditionally accepted by linguists (out of common sense) between the 'system' and 'use' of the language, both in its classical version of Saussure's opposition between 'langue' and 'parole,' and in its neoclassical version of Chomsky's opposition between 'competence' and 'performance.' The adherence to these two categories enables linguists to exorcize the fetish of an explanatory autonomy, by confining the pertinence of Marxism to the illustration of the social function of a language. By the contrast, in Rossi-Landi's view, those abstractions are useful only if they are rooted in the ground of 'common speaking,' which defines historically the linguistic *a priori* of the human being. The philosophical methodology of 'common speaking,' which was later generalized in a semiotic methodology of 'common semiosis' by Rossi-Landi, achieves the Marxist theory target of unveiling the ideological consistency of the 'logosphere' and clarifies the mediating role that sign systems play between the economic basis and the super structures of society.

What Shall We Do?

The Marxist perspective, however narrow it may appear, binds those who study linguistic problems to historical–dialectical materialism and obliges them to consider the connections between linguistic theory and the theory of praxis as being relevant. This double bond results in the urgent need to explore the linguistic signs' ideological texture. But for the linguist, the adherence to such an explanatory route entails the commitment to carry out his own language investigations according to an emancipatory project concerning the potentials of human beings. To be a Marxist in linguistics means to adopt an intrinsically debunking perspective of the relationships of social control that are formed and/or expressed in the language. Of course, it is not necessary to be a Marxist to work out a critical and emancipatory linguistics, but the opposite is true: it is necessary to take a critical attitude to be authentically Marxist in linguistics. Marxism

aims at putting a sort of 'metasemiotics,' meant as a critical theory of ideologies, at the basis of the language sciences. This perspective is shared by those (such as the late Pierre Bourdiese) who try to use Marxian categories (class, commodity, labor, surplus value, alienation) in the analysis of the relations of linguistic reproduction in society, and by those who take only a critical stance from Marxism, thinking that this is enough to perfect the technical solutions provided by linguistic knowledge. Both 'revolutionaries' and 'reformers' share the same desire to look for a small red petal in the white cup of reflexation on language.

Mass Expressions

H Bunt, Katholieke Universiteit Brabant, Le Tilburg, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

By 'mass expressions' one usually means expressions formed with so-called mass nouns, words like *water, rice, poetry,* and *garbage*, which differ morphologically and syntactically from count nouns, like *book, apple, chair,* and *house,* in that they do not have both a singular and a plural form and differ in the possible combinations with numerals, determiners, and adjectives. In particular, mass nouns do not admit combination with numerals, with the indefinite singular article, and with a range of quantifiers: **a water, *both rice, *five poetry, *many garbage, *several music*. Count nouns, on the other hand, do not combine well with certain quantifying adjectives, such as English *much* and *little*; Spanish *mucho* and *poco*; or Danish *meget* and *lidt*, which combine only with mass nouns. In contrast with count nouns, mass nouns allow the formation of determinerless singular noun phrases: *There's furniture in this room* versus **Theres chair in this room*. Such bare NPs are often called 'mass terms' and include phrases like *imported furniture, eau de cologne, mousse au chocolat, orange juice from Brazil*, and *refined pure Cuban cane sugar.*

The count/mass distinction is found in many languages but is not universal and has different manifestations in different languages. The Hopi language has been mentioned by Whorf (1939) as a language that has no mass nouns, and several Asian languages, such as Chinese (Mandarin Chinese) and Japanese, do not mark the count/mass distinction and have been claimed to have only mass nouns (Sharvy, 1978). Also, what is described by a count noun in one language may be described by a mass noun in another; e.g., English *fruit* is a count noun, whereas Dutch *fruit* is a mass noun (*a fruit* can be translated either as *een stuk fruit* (*a piece of fruit*) or as *een vrucht*. In English, by far the majority of mass nouns aremorphologically and syntactically singular; a minority of mass nouns are syntactically plural. A plural example is *measles*: it would be funny to ask **How many measles have you got* (except maybe in a conversation between two doctors, as a way of referring to measles patients). In other languages, plural mass nouns are quite frequent – e.g., in Swahili the word for *water* is

By 'mass expressions' one usually means expressions formed with so-called mass nouns, words like *water, rice, poetry,* and *garbage*, which differ morphologically and syntactically from count nouns, like *book, apple, chair,* and *house,* in that they do not have both a singular and a plural form and differ in the possible combinations with numerals, determiners, and adjectives. In particular, mass nouns do not admit combination with numerals, with the indefinite singular article, and with a range of quantifiers: **a water, *both rice, *five poetry, *many garbage, *several music*. Count nouns, on the other hand, do not combine well with certain quantifying adjectives, such as English *much* and *little*; Spanish *mucho* and *poco*; or Danish *meget* and *lidt*, which combine only with mass nouns. In contrast with count nouns, mass nouns allow the formation of determinerless singular noun phrases: *There's furniture in this room* versus **Theres chair in this room*. Such bare NPs are often called 'mass terms' and include phrases like *imported furniture, eau de cologne, mousse au chocolat, orange juice from Brazil*, and *refined pure Cuban cane sugar.*

The count/mass distinction is found in many languages but is not universal and has different manifestations in different languages. The Hopi language has been mentioned by Whorf (1939) as a language that has no mass nouns, and several Asian languages, such as Chinese (Mandarin Chinese) and Japanese, do not mark the count/mass distinction and have been claimed to have only mass nouns (Sharvy, 1978). Also, what is described by a count noun in one language may be described by a mass noun in another; e.g., English *fruit* is a count noun, whereas Dutch *fruit* is a mass noun (*a fruit* can be translated either as *een stuk fruit* (*a piece of fruit*) or as *een vrucht*. In English, by far the majority of mass nouns aremorphologically and syntactically singular; a minority of mass nouns are syntactically plural. A plural example is *measles*: it would be funny to ask **How many measles have you got* (except maybe in a conversation between two doctors, as a way of referring to measles patients). In other languages, plural mass nouns are quite frequent – e.g., in Swahili the word for *water* is

the plural mass noun *maji*; in Italian the many pasta varieties are syntactically plural, as they are when imported in other languages. One should, for example, say *How much spaghetti do you want* rather than **How many spaghetti do you want*, just as in Italian (*Quanto spaghetti…*; **Quanti spaghetti…*). A morphologically remarkable phenomenon in Dutch is the formation of diminutive forms of mass nouns to refer to portions with certain properties of the stuff that the mass noun refers to. For example, the mass nouns *snoep* (candy), *drop* (licorice), *chocola* (chocolate), *plastic*, *papier* (paper), and *brood* (bread) have the diminutive forms *snoepje, dropje, chocolaatje, plasticje, papiertje,* and *broodje*, which are count nouns referring to particular types of physically well-defined pieces of candy, licorice, chocolate, plastic, paper, and bread, respectively. The interesting point is that diminutive forms of mass nouns differ systematically from those of count nouns in that diminutive count nouns, as opposed to mass noun diminutives, invariably refer to small exemplars in the set of objects denoted by the count noun. For example, *appeltje* and *boekje* refer to small apples and little books, but the diminutive form of a mass noun, like *broodje* or *plasticje*, refer not to a small piece of bread or plastic but to specific pieces, like a roll and a folder for storing papers.

While the count/mass distinction as just outlined may seem intuitively clear, it is difficult to make the distinction precise, especially to make it sufficiently precise for incorporation in a formal grammar. For example, while *apple* may seem a clear example of a count noun, it is possible to say things like *Don't put too much apple in the salad*, using *apple* as a mass noun. David Lewis has invented a hypothetical device to show that every count noun can be used as as a mass noun. This device, the Universal Grinder, can take as input any objects, denoted by a count noun, like apples, books, or crocodiles; it grinds these and spits out the stuff that the objects are made of: apple-stuff, book-stuff, crocodile-stuff. This machine could be said to turn *apples* into *apple, books* into *book*, and *crocodiles* into *crocodile* (Lewis, 1983). One can also imagine a device that works in the other direction. This device, which we might call the Universal Packer, takes as input a continuous stream of any stuff that a mass term *M* may refer to, and outputs packages containing amounts of *M* that are appropriate in a given context. This device illustrates that one can in general construct a count use of a mass noun by finding a context in which the stuff that the mass noun normally refers to comes in certain standard portions, like cups of coffee in a restaurant, where it is quite common to speak of *two coffees*.

These considerations show that virtually every count noun can be used as a mass noun and *vice versa*. We should therefore not classify nouns as count or mass but instead view the count/mass distinction to be one of different ways of using nouns, or perhaps not even as a syntactic or morphological distinction but as a semantic one. Intuitively, the fundamental difference between a mass noun like *applesauce* and a count noun like *apple* is that there is a clear notion of what is one apple, but there's no clear notion of what is one applesauce. In the words of Jespersen (1924): "There are many words which do not call up the idea of some definite thing with a certain shape or precise limits. I call these *mass words*." Or as Quine (1960) put it: "Inherent in the meaning of a count noun, like 'apple' is what counts as one apple and what as another….such terms possess built-in modes of dividing their reference,…while mass nouns do not divide their reference." A common way of expressing this is that count nouns 'individuate' their reference, while mass nouns do not.

The non-individuating way of referring that is characteristic of mass nouns closely relates to the phenomenon that mass nouns can be used to refer to each of several objects as well as to the whole formed by these objects. For example, in a situation where there are several puddles of water on the floor, the term *water* in the sentence *Please mop up the water on the floor* may refer to the individual puddles as well as to the totality of all the water formed by the puddles. This phenomenon is known as 'cumulative reference': "Any sum of parts that are water is water" (Quine, 1960). Similarly, suppose one is served a bowl of rice; when one has eaten half of *the rice in the bowl*, what remains would also be called *rice in the bowl*. In general, for a mass noun *M*, any part of something that is *M* is again *M*. This phenomenon is called 'distributive reference.' The term 'homogeneous reference' has been used both as being synonymous with distributive reference and as denoting the combination of cumulative and distributive reference.

The property of distributive reference has been a matter of discussion among linguists and philosophers. Quine (1960) has rejected the idea that every part of something to which a mass noun may refer, may also be referred to by the noun. He notes that "there are parts of water, sugar, furniture too small to count as water, sugar furniture," since the parts of an H_2O molecule are not water, the legs of a chair are not furniture, and the parts of a grain of sugar would perhaps not be called sugar. Instead, he posits the 'Minimal Parts Hypothesis,' which says that for each mass noun *M*, there is a specific minimal size

that parts of its referent may have in order to count as *M*. There is not much support for this position, however; semanticists generally agree that mass terms should be treated as referring homogeneously, in spite of the fact that their referents in the physical world may have minimal parts. In the standard formalization of count noun meanings, the intuition that count nouns individuate their reference is captured by construing the extension of a count noun as the set of all individuals that correspond to the built-in individuation of its reference. So *apple* refers to the set of all apples. Since a mass noun does not individuate its reference, this leads to the question what kind of things mass nouns denote. Many authors on mass terms believe that the answer to this question requires something else than sets. Quine (1960), Burge (1972), Moravcsik (1973), Ojeda (1993), and several others proposed to make use of mereology, a theory of non-atomic part-whole structures that has been developed as an alternative to set theory (Lesniewski, 1929; Leonard and Goodman, 1940); Bunt (1979, 1985) proposed to use part-whole structures called 'ensembles,' defined in an extension of standard set theory called 'ensemble theory' (see also Lewis, 1991); Parsons (1970) proposed an altogether different notion of 'substances.'

The idea that mass terms do not individuate their references explains why they cannot be combined with numerals: one wouldn't know what to count, so the numerical information would make no sense, and neither would quantifiers, like *several, many, both*, that presuppose countability. As mass terms do not refer to well-delineated objects, it would also be strange to apply adjectives describing properties like shape, size, or weight to mass nouns. This is confirmed by the fact that it is strange to speak of **small wine, *square water*, or **heavy sugar*. (And *heavy water* cannot be used to refer to water that is heavy, but only to refer to the substance deuterium oxide (D_2O), formed by oxygen and the hydrogen isotope deuterium, of atomic weight 2.) It has therefore been suggested that a distinction be made between count and mass adjectives, depending on whether the adjectives share with mass nouns the property of referring homogeneously (Bunt, 1980; cf. Moravcsik). For instance, *square* refers neither cumulatively nor distributively, since the whole formed by two square objects is in general not square, nor are the parts of a square object; *heavy* refers cumulatively but not distributively; and *small* refers distributively but not cumulatively.

Ter Meulen (1980) suggested a count/mass distinction among verbs, depending on whether a verb refers distributively – that is, whether it denotes events that have sub-events that could be described using the same verb. Performance verbs, like *write* and *reach*, would be count verbs, whereas activity verbs, such as *travel* and *think*, would be mass verbs. Syntactic phenomena that support this distinction are that it is strange to say that **Harry was reaching the airport for an hour* while it is fine to say that *Harry was traveling to the airport for an hour*, and, relating to the use of mass terms as direct objects, it is strange to say that **Alice was writing a letter for an hour* but there's nothing wrong with *Alice was writing letters for an hour*.

It may be noted that some of the above observations on mass nouns do not really apply to *all* mass nouns. There is a subclass of mass nouns that do in fact individuate their references; examples in English are *furniture, cattle, clothing, footwear, luggage*. Using Quine's terminology, inherent in the meaning of *furniture* is what counts as *one piece of furniture*. This may explain why such nouns can be modified by adjectives that do not refer homogeneously, as in *small furniture, heavy furniture*. Quantification for these nouns is also different from that for other mass nouns. Whereas *All the water in this area is clean* says that every water part that you can take in this area is clean, *All the cattle in this area have been vaccinated* clearly applies only to animals, not to arbitrary cattle parts. A related morphological phenomenon is that mass nouns of this kind in Dutch do not admit a diminutive form (for example, **meubilairtje, *veetje, *kledinkje, *schoeiseltje, *bagagetje*) – which makes sense, since in these cases the mass noun itself already denotes individuals of the kind that the diminutive form would otherwise denote. Moreover, whereas mass nouns in general have syntactically much in common with plural count nouns, the ones in this particular subclass are semantically no different from count nouns. It has therefore been suggested they be assigned to a separate category, called 'collective' mass nouns (Bunt, 1985).

Mass terms are a challenge to the formal linguist, not only because it is difficult to pin down the count/mass distinction on morphological and syntactic grounds but also because they call for a logical representation of the intuitions about non-individuating reference in such a way that sentences involving mass expressions are systematically assigned correct semantic interpretations through the application of a set of rules in a formal grammar.

Concerning the first part of this challenge, Pelletier and Schubert (1995) have argued that the count/mass distinction can be formalized in two ways: in terms of *occurrences* of nouns and as different *senses* of nouns. An occurrence approach characterizes the use of a noun syntactically as 'count' or 'mass.' An

implementation in a formal grammar would typically assign features 'count' and 'mass' to occurrences of nouns and certain other expressions. By contrast, a sense approach considers all nouns to be just nouns, avoiding any 'count' or 'mass' labeling, and interprets a noun occurring in a certain syntactic ('mass' or 'count') context in its 'mass' or in its 'count' sense. Since virtually every noun can be used either way, the main virtue of an occurrence approach is not to assess the syntactic well-formedness of expressions but rather to characterize the syntactic environments that force one interpretation of the noun or the other. For instance, characterizing the quantifier *much* as 'mass,' we can force the occurrence of *apple* in *not too much apple* to be interpreted as apple-stuff, rather than individual apples. Some authors have suggested that finer distinctions be made among nouns than count/mass (or count/mass/collective), depending on the noun's syntactic preferences for occurring in certain syntactic environments. According to the "noun countability preferences" of Allan (1980), Bond *et al*. (1994) distinguish, besides pure count and mass nouns, among plural-only nouns (like *scissors, pants*), easily convertible count nouns (like *cake, stone*), and easily convertible mass nouns (like *beer, coffee*). This may be of practical use, e.g., in machine translation (Baldwin and Bond, 2003) or in language learning (Nagata *et al*., 2005).

Concerning the second, semantic part of the challenge, Link (1983) and Landman (1991) have suggested that the models for a model-theoretic semantics of natural language should include a non-atomic Boolean algebra (or, more specifically, a join semi-lattice) supporting part-whole structures without minimal parts as semantic interpretations of mass terms. Such a structured model can be used to assign logically adequate interpretations to sentences with mass terms – i.e., interpretations that have the desired logical properties (such as rendering *Water is water* necessarily true, and supporting inferences like *This puddle is water, Water is transparent*, therefore *This puddle is transparent,* but not supporting the inference *Water is scarce here*, *This is a puddle here*, therefore *This puddle is scarce here*).

The fundamental question of what kind of thing a mass noun denotes is not answered in these formal approaches, other than to say that mass terms have denotations figuring in a non-atomic part-whole structure (which would be formally correct only for noncollective mass terms). The use of mereological wholes for these denotations, which many language philosophers have embraced, does provide non-atomic part-whole structures but has the drawbacks that mereology is an alternative to set theory and that mereological concepts as such do not fit in set-theoretical frameworks. In this respect, the use of ensemble theory, which formalizes atomic, non-atomic, and partly atomic part-whole structures within an extension of standard set theory, offers better possibilities for an elegant, integrated treatment of the semantics of mass expressions (cf. Lewis, 1991).

Mass Nouns, Count Nouns, and Non-count Nouns: Philosophical Aspects

H Laycock, Queen's University, Kingston, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Linguists often distinguish 'count nouns' (CNs) and 'non-count nouns' (NCNs) (designated as 'count+' and 'count' nouns, respectively). The distinction, though hardly simple, is both exhaustive and entirely natural. In philosophical writings, by contrast, it is more usual to posit a dichotomy of 'count nouns' and 'mass nouns' (MNs) – a dichotomy that is very commonly (and however vaguely) supposed to be of metaphysical or ontological significance. But this dichotomy, unlike that of CNs and NCNs, is deeply problematic; here, in consequence, I speak only of a **supposed** dichotomy of CNs and MNs, and by the same token, of a **putative** category of MNs.

Plural Count Nouns and Non-count Nouns

There is a certain kinship between NCNs and plural CNs, a kinship that has in recent years attracted some attention; see e.g., Schein (1994). What is less widely appreciated is the basis of this kinship in the actual semantic status of NCNs. Laycock (1998) urged that since CNs, or their occurrences, are semantically **either** singular or plural, to be non-count is simply to be **neither** singular nor plural. Non-count nouns are then semantically non-singular, and it is this that underlies their kinship with the plural (plural nouns themselves, it is evident, are non-singular). But being non-plural, the non-count form is never, unlike that of many plural sentences, reducible to the canonical singular form. The relationships between the semantics of CNs and NCNs may thus be simply represented in **Table 1** (Laycock, 1998). The inclusion of a contrast between 'clothes' and 'clothing' alongside that between 'apples' and 'water' serves to emphasize the point that the singular/non-singular contrasts in general (and not simply the singular/plural contrasts) are first and foremost **semantic** as opposed to **metaphysical** or ontic contrasts (it being assumed that the 'clothes'/'clothing' contrast itself is purely a semantic one).

Non-count nouns are to be classed as semantically non-singular, simply by virtue of being non-count.

Table 1 Semantics of count nouns versus non-count nouns

	1. **Singular** ('one')	2. **Non-singular** ('not-one')
3. **Plural** ('many')	– – –	'things' 'apples' 'clothes'
4. **Non-plural** ('not-many')	'thing' 'apple' 'piece of clothing'	'stuff' 'water' 'clothing'

Mass Nouns, Count Nouns, and Non-count Nouns: Philosophical Aspects

H Laycock, Queen's University, Kingston, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Linguists often distinguish 'count nouns' (CNs) and 'non-count nouns' (NCNs) (designated as 'count+' and 'count' nouns, respectively). The distinction, though hardly simple, is both exhaustive and entirely natural. In philosophical writings, by contrast, it is more usual to posit a dichotomy of 'count nouns' and 'mass nouns' (MNs) – a dichotomy that is very commonly (and however vaguely) supposed to be of metaphysical or ontological significance. But this dichotomy, unlike that of CNs and NCNs, is deeply problematic; here, in consequence, I speak only of a **supposed** dichotomy of CNs and MNs, and by the same token, of a **putative** category of MNs.

Plural Count Nouns and Non-count Nouns

There is a certain kinship between NCNs and plural CNs, a kinship that has in recent years attracted some attention; see e.g., Schein (1994). What is less widely appreciated is the basis of this kinship in the actual semantic status of NCNs. Laycock (1998) urged that since CNs, or their occurrences, are semantically **either** singular or plural, to be non-count is simply to be **neither** singular nor plural. Non-count nouns are then semantically non-singular, and it is this that underlies their kinship with the plural (plural nouns themselves, it is evident, are non-singular). But being non-plural, the non-count form is never, unlike that of many plural sentences, reducible to the canonical singular form. The relationships between the semantics of CNs and NCNs may thus be simply represented in Table 1 (Laycock, 1998). The inclusion of a contrast between 'clothes' and 'clothing' alongside that between 'apples' and 'water' serves to emphasize the point that the singular/non-singular contrasts in general (and not simply the singular/plural contrasts) are first and foremost **semantic** as opposed to **metaphysical** or ontic contrasts (it being assumed that the 'clothes'/'clothing' contrast itself is purely a semantic one).

Non-count nouns are to be classed as semantically non-singular, simply by virtue of being non-count.

Table 1 Semantics of count nouns versus non-count nouns

	1. **Singular** ('one')	2. **Non-singular** ('not-one')
3. **Plural** ('many')	– – –	'things' 'apples' 'clothes'
4. **Non-plural** ('not-many')	'thing' 'apple' 'piece of clothing'	'stuff' 'water' 'clothing'

And given this, both quantification and denoting that involve such nouns also must be semantically non-singular. In the case of quantification, the non-singularity of NCNs is reflected in their obvious non-acceptance of singular quantifiers – in the fact that we may speak (as with plural nouns) of ***all*** *water,* ***some*** *water,* and ***more*** *water* but not in the singular of ***a*** *water,* ***each*** *water,* or ***one*** *water. Any, all,* and *some* interact with NCNs much as with essentially plural nouns; and *All* ***n V*** *made of polyester* and *The* ***n*** *in the warehouse* ***V*** *made of polyester* are related in essentially the same way, whether ***n*** is replaced by *clothes* and ***V*** by *are*, or ***n*** is replaced by *clothing* and ***V*** by *is*. The implications of the non-singularity of NCNs for the semantics of sentences containing definite descriptions and referential expressions are complex and extend beyond the remit of these brief remarks. However, the relatively common **mereological** interpretations of non-count reference take it to be semantically singular, designating individual 'parcels of stuff' or 'quantities' (see e.g., Bunt, 1985), and the non-singularity of NCNs is evidently not consistent with approaches of this type. Indeed, difficulties with the singularity assumption have been noted precisely in relation to Russell's theory of singular descriptions, which maintains, as he puts it, that ***the*** "in the singular" involves **uniqueness** (Russell, 1956: 176); see e.g., Montague (1973) and Laycock (1975).

The Concept 'Mass Noun' and Its Supposed Criterion

Turning now to so-called MNs, perhaps the first use of an expression of the MN genre occurs in Jespersen (1924), who wrote of 'mass words,' contrasting these with what he called 'countables' or 'thing words.' And the thought that such words had a distinct metaphysical significance received the following expression in his work:

> There are a great many words which do not call up the idea of some definite thing with a certain shape or precise limits. I call these 'mass-words'; they may be either material, in which case they denote some substance in itself independent of form, such as … water, butter, gas, air, etc., or else immaterial, such as … success, tact, commonsense, and … satisfaction, admiration, refinement, from verbs, or … restlessness, justice, safety, constancy, from adjectives. (Jespersen, 1924: 198)

Subsequent writers typically differ from Jespersen in treating the domain of 'mass words' as one of **concrete** nouns exclusively; but insofar as these latter nouns are concerned, Jespersen's approach would seem to represent the norm. Thus if the question is raised, of what semantic element constitutes the putative MNs as a distinct category of concrete nouns, the answer tends to be that it is precisely some such element of 'form-independence' – an absence of 'criteria of distinctness' (Hacker, 1980) or of a 'boundary-drawing,' 'individuating,' 'form-specifying,' or 'reference-dividing' component in their meaning (Quine, 1960; Chappell, 1971; Talmy, 1978; Langacker, 1987; Jackendoff, 1991; Kleiber, 1997).

In this regard, Quine nicely represented the common view. To learn a "full-fledged general term" like 'apple' it is not enough, so he remarks, to learn "how much of what goes on counts as apple": "we must learn how much counts as **an** apple, and how much as another. Such terms possess built-in modes … of dividing their reference" (1960: 91). So-called 'mass terms,' in contrast, do not thus divide their reference. Water, Quine wrote, "is scattered in discrete pools and glassfuls… still it is just 'pool,' 'glassful,' and 'object,' not 'water'… that divide their reference" (1960: 91). If such a noun is used to individuate a full-fledged, 'substantial' object, it needs an individuating adjunct. There is no learning "how much counts as **some** water and how much counts as some **more**"; there is no such distinction to learn. Whereas any sum of parts that are each an apple is not another apple, this lack of a boundary-drawing element confers upon the putative MNs what Quine called "the semantical property of referring cumulatively": "any sum of parts which are water is water," as he puts it. I shall call this widely accepted criterion for distinguishing the putative category of MNs from CNs, in whichever of the various equivalent forms it is fleshed out, the 'no built-in reference-division' (no-RD) criterion. The key assumption that underlies the supposed dichotomy of CNs and MNs is, then, that possible borderline cases apart, there **is** a specific and more or less determinate category of concrete nouns that answers to the no-RD criterion – the putative category of MNs, to be precise.

Now, whereas the range of nouns that are categorized as MNs varies significantly from one writer to another, all the nouns that are thus categorized are in fact (and must be) NCNs. But here my concern is not with the nouns themselves; it is just with the putative **category**, as determined by the no-RD criterion, to which they are said to belong. And insofar as the use of the term 'MN' rests on this criterion, the contrast of CNs and MNs is quite fundamentally misconceived; the reality is that no such category as that of MNs exists. There are, on the contrary, two semantically distinct categories of nouns that answer to the no-RD criterion – concrete NCNs and concrete plural CNs (a fact that, given the common non-singularity of these two categories, is not altogether surprising).

An Illusory Criterion

Although the kinship of the putative MNs with concrete plural CNs is commonly remarked, it is less often noted that the no-RD criterion itself applies identically to the plural nouns. Thus, for instance, although we learn "how much counts as **an** apple, and how much as another," there is no learning "how much counts as **some** apples, and how much as **more** apples" – there is no such distinction to learn. Although the singular *apple* applies to just one apple at a time, *apples* sets no limits on the count of apples. It is not the meaning content of the plural noun itself that sets whatever limits there may be; it is contingencies of context, including acts of demonstration – for example, ***these** apples* – that demarcate the subject matter of a discourse. *Apples* provides no criteria of distinctness or boundaries for what it collectively applies to – it does not, *qua* plural, carve what it applies to 'at the joints.' To play the role of designating full-fledged objects, each of which is apples, *apples,* much like *water,* needs an individuating adjunct ('heap of _____', 'bag of _____,' or the like). Thus, if water may be characterized as 'form-indifferent', then apples, too, collectively, may be so characterized. Much as the water in a glass might be spilled or dispersed and survive, so, too, might the apples in a bag. And so far as Quine's 'cumulative reference' is concerned, whereas any sum of parts each of which is **an** apple will not be **another** apple, any sum of parts that are **apples** will simply be more **apples**.

The appearance of a dichotomy between CNs and the putative MNs then arises purely and simply because the chosen occurrences of CNs are **singular** exclusively – plural nouns are nowhere in the picture – and once plural occurrences of CNs are factored in, the supposed dichotomy with CNs disappears. Insofar as the no-RD criterion is conceived as definitional of the distinctive status of some putative 'metaphysically interesting' class of nouns, this putative category of nouns is ill-defined or ill-conceived, and talk of such a category is best abandoned. The only categories that are to be legitimately contrasted with CNs are those of NCNs as such and of the various subcategories of NCNs. And although metaphysically interesting distinctions between CNs and some sub-groups of NCNs certainly do exist, such distinctions have nothing to do with the spurious category of MNs. They are not, that is, a function of the no-RD criterion, obtaining as they do between various groups of nouns, **all of which** satisfy that criterion. (It is then hardly surprising that what is supposed to count as an MN varies significantly from one sponsor of the concept to another: the no-RD criterion does zero work, and it is rather individual metaphysical intuitions that actually determine whether a given NCN is to be assigned to the putative category or not.) What the no-RD criterion reflects is simply the contrast between CNs in the singular, and non-singular nouns altogether generally, whether NCNs or plural CNs. But the central contrast in this domain is rather one between distinct forms of non-singularity – the plural, and the non-count – and as such, to repeat, this contrast is purely a semantic one.

The point retains its relevance at the formal level of the contrast between 'stuff' and 'things' themselves. These words are formally NCNs and CNs, respectively; but whereas the contrast of stuff and things is not infrequently treated by sponsors of the 'MN' category as if it were a metaphysical distinction, the fact is that 'stuff' may be and is applied to **things** without restriction ('the stuff in the basement' may just denote a pile of pots and pans, garden tools, old chairs, and bicycles).

The Non-metaphysical Goods

We are left, then, with an essentially semantic contrast between concrete CNs and NCNs. And what this semantic contrast embodies are distinct modalities for the determination and specification of amount or quantity. Count nouns embody one such modality – trivially, that of counting through the use of natural number-related words – *one horse, so many things, too few clothes, a dozen eggs, a single professor,* etc.; and in this intuitive sense, counting is applicable to the denotata of CNs **exclusively**. Non-count nouns, by contrast, involve a form of what is naturally called 'measurement': *so much cotton, too much stuff, so little water, five tons of clothing,* etc. And although the denotata of NCNs may be **only** measured and not also counted, measurement as such is applicable to the denotata of both NCNs and CNs alike. We may, for instance, speak both of *75 ccs of water* and *75 ccs of poppy seeds*, both of *5.5 kilos of clothing* and *5.5 kilos of apples*. Furthermore, it seems clear that in contrast with counting, **any** real number can in principle be assigned to the measure of an amount of something. The concept of weight, for instance, is such that it is intelligible to assign a weight of n kilos (where n represents an integer), or of $n \times \pi$ kilos, to a quantity of snow (or rice, apples, clothing, underwear, water, etc.).

Intuitively, then, counting may be described as the determination of 'discrete' or 'discontinuous' quantity and measuring the determination of 'continuous' quantity. Of the two, discrete quantity seems privileged: there is exactly one non-relative way of determining the quantity of, say, eggs in a carton, which is

precisely to count them. But there is no such unique way of determining, say, the quantity of cotton in a warehouse; this might be done, e.g., by volume, or by weight, or indeed by counting the number of bales; and these different measures cannot be expected to be correlated in any uniquely determinate way.

The contrast of discrete and continuous quantity is not directly ontological – it is not a matter of whether something consists of discrete 'bits' (visible or otherwise) or not. We may count planets, eggs, or horses to determine their number; we may weigh apples, snow, or clothing to determine their amount. The non-ontic nature of the contrast is perhaps especially striking in the juxtaposition of such words as the CN *clothes* (or, e.g., *boots and shoes*) and its cognate collective NCN *clothing* (or *footwear*). Although *clothing* represents continuous quantity and *clothes* discrete quantity, to say that **there is** clothing here or there is to say no more than that **there are** clothes here or there. In this respect, there is good sense in the remark of Quine: "The contrast lies in the terms and not in the stuff they name ... 'shoe' ... and 'footwear' range over exactly the same scattered stuff" (1960: 91).

The contrast 'lies in the terms': although there are **units** of clothing, furniture, etc. (individual pieces of clothing, pieces of furniture, etc.) – indeed, while collective nouns like *clothing* and *furniture* might be said to be ontologically **equivalent** to cognate CNs – such NCNs are no less **semantically** non-count than non-collective nouns like *water* and *mashed potato*. Thus, although there is a straightforward sense to talk of the smallest **number** of clothes – a single item of clothing – there is no good sense to talk of the smallest **amount** of clothing – is one woolen winter coat the same amount of clothing as a single nylon stocking? In absolute terms, I've suggested, talk of amounts in relation to the denotata of NCNs (collective or otherwise) is simply ill-defined; and relative to some particular dimension such as weight or volume, there is no semantic rationale for specifying minimum amounts.

But although not directly ontological, the contrast of discrete and continuous quantity involves the **possibility** of certain ontic contrasts. Counting truistically involves discrete units; and although what is measured may consist of discrete units, measurement as such does not require it, and there are ontic category-differences **within** the semantic category of NCNs. Thus, contrast the two groups of NCNs (a) *furniture, footwear,* and *clothing,* and (b) *rubble, sand,* and *snow,* with what may be called the 'pure' NCNs of group (c): *mashed potato, wine,* and *water.* The collective nouns of group (a) may be said to be 'object-involving,' in that they are semantically 'atomic' – there are units of furniture, footwear, and clothing that are not divisible into smaller units of furniture, footwear, and clothing. It is part of the **meaning** of such an NCN that like a typical CN, it ranges over discrete pieces, units, or elements of what the NCN denotes; indeed the very **identity** of some furniture is not to be distinguished from that of some pieces of furniture. For this reason, the identity of the denotata of group (a) nouns is independent of the identity of the materials of which those denotata are composed; some furniture can survive some loss of constituent materials – wood, cloth, stuffing, etc. – and remain the same (arguably, indeed, it is conceivable that all of the materials of some furniture could be replaced over time while the furniture retains its identity). But the same can hardly be said of the nouns in groups (b) and (c).

Now group (b), though not thus atomic, are object-involving in that they may be said to be 'semantically particulate': it is part of their meaning that what these words denote consists of discrete grains, flakes, bits, etc. – the difference being that the identity of some sand (snow, rubble, etc.) is **not** dependent on that of certain particular grains, flakes, or bits; it may be further crushed or pulverized and yet remain the same. In contrast with groups (a) and (b), however, no such object-involving concepts enter into the meanings of the group (c) terms. Whereas, for instance, to say that there is furniture or clothing in some region is to say that there are constituent pieces or units of furniture or clothing in that region, to say that there is wine or mashed potato in some region is not to say that there are objects that can be characterized as 'pieces' or 'units' of wine or mashed potato in that region. In the nature of the case, there is here no comparable notion of a constituent piece or unit.

Masterman, Margaret (1910–1986)

V Eisenlauer, Universität Augsburg, Augsburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Masterman was a pioneer in computational linguistics. Her ideas and proposals in research on artificial intelligence and machine translation were far ahead of her time and made a significant contribution to this field.

Born in London in 1910, she was educated at Hamilton House, Tunbridge Wells, the Institute Brittanique in Paris, and Newnham College. At Cambridge she studied modern and medieval languages and also philosophy as a student of Wittgenstein. Married to Richard Bevan Braithwaite, professor of moral philosophy at Cambridge University, she published under her maiden name Masterman and became a lecturer in the moral sciences faculty on philosophy and languages in 1959. In addition to her profound research on machine translation, Masterman also published various novels and plays, established a society for women graduates and academics (known as the 'Dining Group') in 1950, and became involved in the publication of the journal *Theoria to Theory*, first published in 1966. Furthermore, she was a fellow founder of Lucy Cavendish College in Cambridge. She died in 1986 in Cambridge, at the age of 75.

Masterman's research reflects the intellectual stimulus of two persons in particular: while her empirical examination of language function can be traced back to the ideas of Wittgenstein, the rather formal theories she considered in language processing show the strong influence of her husband, the eminent logician and philosopher of science, Richard Braithwaite.

Her major contribution to the field of artificial intelligence and machine translation developed as part of the work of the Cambridge Language Research Unit (CLRU). As the director of that unit, she was primarily interested in semantic problems of machine translation and proposed the use of a *thesaurus* (a structured conceptual semantic classification of vocabulary) as a powerful tool for word sense disambiguation in language processing programs. In the same vein as Francis Bacon, Thomas Hobbes, John Wilkins, and other such authors of a universal language in the 17th century, Masterman believed that an adequate theory of the structure of thesauri would make explicit certain underlying structures of the semantic relations in a natural language, so that semantic primitives would emerge naturally. For some years Masterman explored the so-called lattice theory

Masterman was a pioneer in computational linguistics. Her ideas and proposals in research on artificial intelligence and machine translation were far ahead of her time and made a significant contribution to this field.

Born in London in 1910, she was educated at Hamilton House, Tunbridge Wells, the Institute Brittanique in Paris, and Newnham College. At Cambridge she studied modern and medieval languages and also philosophy as a student of Wittgenstein. Married to Richard Bevan Braithwaite, professor of moral philosophy at Cambridge University, she published under her maiden name Masterman and became a lecturer in the moral sciences faculty on philosophy and languages in 1959. In addition to her profound research on machine translation, Masterman also published various novels and plays, established a society for women graduates and academics (known as the 'Dining Group') in 1950, and became involved in the publication of the journal *Theoria to Theory*, first published in 1966. Furthermore, she was a fellow founder of Lucy Cavendish College in Cambridge. She died in 1986 in Cambridge, at the age of 75.

Masterman's research reflects the intellectual stimulus of two persons in particular: while her empirical examination of language function can be traced back to the ideas of Wittgenstein, the rather formal theories she considered in language processing show the strong influence of her husband, the eminent logician and philosopher of science, Richard Braithwaite.

Her major contribution to the field of artificial intelligence and machine translation developed as part of the work of the Cambridge Language Research Unit (CLRU). As the director of that unit, she was primarily interested in semantic problems of machine translation and proposed the use of a *thesaurus* (a structured conceptual semantic classification of vocabulary) as a powerful tool for word sense disambiguation in language processing programs. In the same vein as Francis Bacon, Thomas Hobbes, John Wilkins, and other such authors of a universal language in the 17th century, Masterman believed that an adequate theory of the structure of thesauri would make explicit certain underlying structures of the semantic relations in a natural language, so that semantic primitives would emerge naturally. For some years Masterman explored the so-called lattice theory

as the underlying formal structure of thesauri and linked this to the notion of a fan as representing the ways in which the senses of words spread out indefinitely into the future. She regarded structures such as lattices, which are applicable to mathematical techniques, as genuine structures and contrasted them with systems, which she saw as formal notations without any mathematical content.

Much of Masterman's research effort was expended on the building of interlingual dictionaries and the establishment of the interlingual semantic components themselves. In 1961 she proposed a list of 100 primitive classifiers, such as *folk*, *stuff*, *thing*, *do*, and *be*, and organized them into a lattice, so that her group defined a conceptual dictionary of 15 000 entries.

Inspired by her CLRU colleague M. A. K. Halliday and his idea that syntactic theory was fundamentally semantic or pragmatic, in later research Masterman investigated basic message structures and described a machine translation model that was grounded in her notion of semantic squares. The basic unit of a semantic square is a coupling of phrases with two stress points, in such a way that the phrases in language A form an analogy with the phrases in language B. It was assumed that a patterning of semantic contrasts, reiterations, and recapitulations appears to underlie argument and paragraph structures and transcends specific language structures. This relationship between stress, reiteration, and semantic information structures remained a focal point of Masterman's further academic research.

Masterman's idea of using the word heads of a thesaurus as a set of semantic primitives for semantic coding and analysis does have a strong correlation with what became well-tested information retrieval techniques.

The continual intellectual stimulus she gave to the research at CLRU inspired many of her colleagues and students, such as Martin Kay, Karen Sparck Jones, Yorick Wilks, and Roger Needham, who became major figures in natural language processing, information retrieval, and computing.

Mathesius, Vilem (1882–1945)

M S Seegmiller, Montclair St College, Montclait, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Vilem Mathesius (1882–1945) was a Czech linguist and the founder and president of the Prague Linguistics Circle. Mathesius specialized in Germanic and Romance studies at Charles University in Prague and later became that university's first professor of 'Anglistics.' He wrote widely on topics in English philology and linguistics, but also on more general topics in linguistic theory. His 1911 paper *On the potentiality of the phenomena of language* was an early classic of European structuralism and echoed some of the ideas expressed in Ferdinand de Saussure's *Course in general linguistics*, in particular the distinction between the synchronic and the diachronic study of language, and that between language and speech.

Mathesius left a considerable body of work on literature and poetics, but his main linguistic interests were in functional syntax and onomatology. He championed the Functional Sentence Perspective (FSP) approach to syntax, which focused on the information structure of sentences rather than phrase structure *per se*. FSP proposes that each sentence consists of a 'theme,' the given or known information, and a 'rheme,' or what is said about the theme. (Other terms for essentially the same concepts are 'topic' and 'comment,' or 'given' and 'new.') In free-word-order languages like Czech, the division of a sentence into a subject and a predicate fails to account for noncanonical arrangements of the words, where almost any order is possible. FSP is intended to account for word-order phenomena by relating it to information structure. The FSP approach has never enjoyed much popularity among linguists who specialize in fixed-word-order languages like English, but it still enjoys wide appeal among Slavic linguists, because the free word order of the Slavic languages seems to lend itself to an FSP perspective.

Although Mathesius himself made several important contributions to linguistics, he will probably be best remembered as the founder of the Prague Linguistic Circle. The Circle started as a monthly gathering of linguists in Prague, who dined together and then heard an invited paper by a prominent colleague. Topics ranged from grammatical theory to psycholinguistics, and engaged central European linguists in discussions of the leading ideas of the time. But the Circle acquired a whole new significance with the arrival of two brilliant Russian émigrés, Nikolai Trubetzkoy and Roman Jakobson. Trubetzkoy and Jakobson were primarily phonologists (although, as is well known, Jakobson's interests in matters of language were almost without boundaries). It was Trubetzkoy and Jakobson's phonological theories, focusing on distinctive features and phonological universals, that left their stamp on the Prague Linguistic Circle and gave rise to the notion of the 'Prague School' as one of the most important schools of European structuralism. Mathesius was the founder of the Prague Linguistic Circle and remained its president until his death in 1945, but it is ironic that his own interests are little associated with the general impression of what the Prague School contributed to our understanding of language.

Matoré, Georges (1908–1998)

N Lioce, Ivo Sint-Andries, Belgium
P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

After studying decorative art and obtaining his *licence* in modern philology and a certificate in Arabic, Matoré embarked on a career as a teacher of French, and later as a literary scholar and a linguist. In the late 1930s, he taught French in Lithuania, where he was arrested by the Soviet secret police. He escaped, was arrested in 1942 by the Gestapo, but released in 1943. Upon his return to France, he started preparing his Ph.D. under the direction of Charles Bruneau. Having obtained his Ph.D. (1946), he became professor first in Besançon (1947–1952), then at the Sorbonne university, where he directed the French civilization curriculum, organizing pedagogical training sessions for teachers of French. He directed several doctoral dissertations at the Sorbonne and at Paris-Nanterre, and continued his teaching well after his retirement in 1979.

As a literary scholar, Matoré was a specialist of modern French literature (17th to early 20th century), dedicating himself to text edition and text commentary (works of Molière, l'abbé Prévost, Théophile Gautier, Honoré de Balzac, and Marcel Proust). He was also an excellent connoisseur of modern art and a music lover, wrote insightful essays on the connection between music, painting, and literature (1973, 1979), and on the representation of space (1962), and produced a film on abstract painting. A specialist of teaching French as a foreign language, he was involved in the elaboration of the *français fondamental*, a basic vocabulary for didactic purposes. As a linguist, he is especially known for his contribution to French lexicology, as a historian (1968) but primarily as a methodological innovator. His thesis (published in 1951) was a study of the French lexicon around 1830, both at a general sociocultural level (as distilled from contemporary newspapers, popular press, etc.) and as specifically reflected in the prose writings of Théophile Gautier (whose vocabulary is thematically analyzed). The methodology adopted in the thesis reflects Matoré's view of lexicological research: it starts from the political, social, economic, and cultural events and innovations that underlie the structure and the changes of the lexicon (apparent from a number of *mots-témoins*, 'witness words,' neologisms that are the embodiment of societal changes), which can be structured in thematic fields around a number of *mots-clés* 'key-words') governing the hierarchical structure of the lexicon (however, the sociocultural frame constructed by the author is not inductively arrived at, and as such the structural 'reconstruction' has an *a priori* and subjective ring). Matoré presented a systematic account of his views in his 1953 book on method in lexicology, where he defines lexicology as a sociological discipline, the specificity of which lies in its word-based orientation: society is explained through its vocabulary. Matoré relegates atomistic word study to what he calls 'lexicography' and concentrates in his 'lexicology' on conceptual or thematic fields, corresponding to the 'world view' of (French) society at a particular period. His last major book publications (1985, 1988) offer a wide-ranging application of his methodology to the vocabulary of French medieval and 16th-century society. Matoré's stand is a structuralist one, but an externalist and not a 'language-internal' (or immanent) one: the structure of the vocabulary of a society at a given time can only be grasped and explained by tracing the interconnection of the lexical system with extra-linguistic data. Such a view implies that linguistic signs, while being arbitrary in their material constitution, are motivated in their content by sociocultural facts.

Matsumoto, Katsumi (b. 1929)

Y Nagashima, Gakushuin University, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Katsumi Matsumoto was born in Nagano, Japan on October 25, 1929. He graduated with a B.A. from the department of linguistics at the University of Tokyo in 1953, and an M.A. from the graduate school there in 1956. He was trained in classical philology and Indo-European comparative linguistics under Harushige Kodzu, late professor of linguistics (*see* **Kodzu, Harushige (1908–1973)**). He was appointed lecturer in linguistics at the University of Kanazawa in 1956, associate professor in 1964, and professor of linguistics in 1975. He studied under W. S. Allen and John Chadwick as a visiting scholar at the University of Cambridge from 1977–1978. He was professor of general linguistics at the University of Tsukuba from 1983 to 1993. Matsumoto was chief editor of *Gengo Kenkyu* from 1983 to 1985 and Japan's representative at the General Assembly of CIPL in 1987. He served as president of the Linguistic Society of Japan from 1991 to 1994.

His major field of study is Indo–European linguistics, especially Ancient Greek, typology, and the genealogical study of Japanese. One of his outstanding and influential contributions to Japanese historical linguistics is his theory on the vowel system of Old Japanese, in which he postulated a 5-vowel system based on internal reconstruction (Matsumoto, 1975b, 1995).
